1 Introduction

From January 2001 to May 2002, world cotton prices fell almost 40 percent, from 64 cents per pound to 39 cents per pound¹. This decline is part of a longer downward trend from the mid-1990s when cotton prices were over 80 cents per pound (see Figure 1). One reason for the recent decline the slowing of worldwide economic growth, which has a greater effect on cotton than grains because clothing is more income-elastic than grains are. As a result, cotton demand has been stagnant at 20 million tons over the last three years. A second factor is that, over 1999-2001, China has expanded output and reduced its government stocks by 2.2 million tons. The subsidized auctions of government stocks, combined with quantitative import restrictions, allowed China to meet growing internal demand with minimal imports. And third, in 2001 the United States had record production and near-record exports in 2001. U.S. exports continue expand in the face of stagnant global demand thanks in part to various types of government assistance provided to cotton farmers² (USDA, 2002a).

The adverse impact of these trends on cotton exporting nations is clear. Particularly affected are several West African nations which rely on cotton exports for a large share of their foreign exchange revenue. In Benin, for example, cotton represents 90 percent of agricultural exports and 60-70 percent of its total exports (excluding re-exports³).

The impact of lower cotton prices on rural poverty, however, is less clear. If cotton is grown mainly by larger farmers with relatively high incomes, then the effect of changes in cotton prices on rural poverty may be modest. Even if cotton is not grown primarily by large farmers, the magnitude of the effect on rural poverty may be small if few farmers grow cotton or if it accounts for a small share of rural income. Assessing the impact of changes in cotton prices on rural poverty requires detailed household survey data on incomes and expenditures, as well as information on linkages between cotton and other sectors in the economy.

This paper examines the impact of changes in cotton prices on rural poverty in Benin. In particular, it has four objectives:

¹ These prices are based on the A-Index cotton price, calculated as the average of the five lowest prices for U.S. cotton in Northern European markets based on a grade of middling 1-3/32 inch fiber length.

² In 1999, cotton farmers in the U.S. received over US\$ 600 million from the production flexibility contract (PFC) program which is untied to production levels. The same year, they received, more than US\$ 1.5 billion in loan deficiency payments and marketing loan gains. Finally, they received about US\$ 600 million in economic and disaster assistance to compensate for low prices and/or poor weather. Cotton exporters and U.S. mills also received roughly US\$ 200 million in "Step 2" user marketing certificates, designed to keep U.S. cotton exports competitive (USDA, 2002b).

³ Re-exports of manufactured goods to Nigeria and other countries accounts for a large share of total exports.

- to describe the living conditions and level of poverty for cotton growers and other farmers in Benin;
- to estimate the short-run impact (before households adjust) of lower cotton prices on the income of cotton growers and on the incidence of poverty in rural Benin;
- to estimate the medium-run, direct impact (after household adjust variable inputs) of lower cotton prices on incomes and poverty in rural Benin; and
- to estimate the total impact of lower cotton prices including the effect on households that do not grow cotton but are affected indirectly by the reduced demand for labor and the reduced purchasing power of cotton farmers

2 Background

The Republic of Benin is a small West African nation of about 6.0 million inhabitants, which covers an area 112 thousand square kilometers. Within this area, only 23 thousand km² (21 percent) is used for agriculture. The southern part of the country has a sub-equatorial climate with bi-modal rainfall averaging 1200 to 1500 mm per year. Maize and cassava are the staple food crops, and the area is densely populated, with up to 300 inhabitants/km². The center is drier (1000 to 1200 mm) and less densely populated, with a diversified agriculture that includes maize, cassava, cowpeas, groundnuts, and cotton. The north is semi-arid (800-1000 mm) and sparsely populated (less than 40 inhabitants/km2). Its rural economy is based on maize, sorghum, millet, yams, cotton, and livestock production.

The per capita gross national product is US\$ 380, placing Benin among the low-income countries of the world. Its per capita income is higher than that of its landlocked neighbors to the north (Niger, Mali, and Burkina Faso), but lower than that of Cameroon and Cote d'Ivoire (World Bank, 2000). The agricultural sector accounts for 38 percent of the gross domestic product and employs about 56 percent of the economically active population.

In 1974, the military government adopted the principles of socialism, nationalizing large formalsector companies, establishing crop marketing boards with monopoly power, creating state farms, and attempting to organize farmers into cooperatives. By the end of the 1980s, an economic crisis was mounting due to falling prices of cotton and oil, the collapse of the mismanaged banking sector, and growing debt. The president renounced Marxism and calle d for a constitutional convention. The convention drafted a constitution that featured democratically elected presidents with four-year terms. In what is considered a model of peaceful democratic transition, the 17-year military leader was voted out of office.

Political reforms coincided with economic reforms as Benin entered into the first of several structural adjustment programs with the International Monetary Fund and the World Bank. In the

agricultural sector, state farms and cooperatives were disbanded, food crop prices and marketing were liberalized, and many state-owned enterprises, including agro-processing enterprises, were privatized or closed (République du Benin, 1997). In January 1994, after several years of signs that the franc CFA (FCFA) was overvalued, it was devalued from 50 FCFA/French franc to 100 FCFA/French franc. Although this imposed hardships on manufacturing firms and consumers that had become accustomed to cheap imports, it stimulated the local production of cotton, rice, and other tradable goods.

Although the cotton sector benefited from the 1994 devaluation, structural reform in cotton marketing was limited. The cotton sector in Benin remained under the control of the state-owned *Societé Nationale pour la Promotion Agricole* (SONAPRA). Private firms were allowed to enter the fertilizer import sector, but SONAPRA continued to manage the importation and distribution of inputs. In cotton marketing, private firms were allowed to compete in cotton ginning, but they continued to rely on SONAPRA to collect the cotton and allocate it among the gins. One of the advantages of retaining this system is that it made it easier for SONAPRA to provide free seed and fertilizer on credit, since its monopsony power in cotton marketing allowed it to enforce repayment of input credits. According to a nationally representative farm survey⁴ carried out in 1998, 97 percent of all cotton growers used fertilizer, all of which was purchased on credit. In contrast, only 24 percent of other farmers used fertilizer, and just 19 percent of these purchases were made on credit (see IFPRI, 2001). In the past two years, Benin has begun to implement more far-reaching reforms of the cotton sector that would reduce the role of SONAPRA and introduce competition in the distribution of inputs and the marketing of cotton. These reforms have been jeopardized, however, by the sharp fall in world cotton prices.

Cotton production in Benin increased from 146 thousand tons in 1990 to 443 thousand tons in 1996. In the late 1990s, the output fluctuated in the range of 350-390 thousand tons per year. Even after declining somewhat from its peak in 1996, the average annual growth rate in cotton production over the 1990s was 10.7 percent. Some of this growth can be attributed to the devaluation of the CFA franc, which allowed farm-level cotton prices to double. It is important to note, however, that cotton production increased substantially even before the devaluation as a result of improvements in the organization of the system of input distribution and marketing.

The economic reforms carried out in the 1990s and the growth in cotton production during this period resulted in concrete benefits for rural households. The 1994-95 *Enquête sur les Conditions de Vie en Milieu Rural* (Survey of Rural Living Conditions) estimated the poverty rate at 33 percent (UNDP-MDR, 1996: 13). Adopting a similar definition of expenditure and the same poverty line (adjusted for inflation), the poverty rate in the 1998 survey was 21 percent. Given differences in methods and samples,

⁴ The IFPRI-LARES Small Farmer Survey is described in Section 3.

one should not put too much weight on this result. However, qualitative questions in the latter survey appear to support the view that rural conditions have improved. According to the IFPRI-LARES survey, 52 percent of the households reported that they were better off at the time of the survey (1998) than in 1992 and only 28 percent reported being worse off (see Table 1). Furthermore, those reporting improvement tended to attribute these gains to economic factors such as crop prices and off-farm income opportunities, while those reporting worsening conditions tended to cite health and weather factors (see Table 2). Cotton farmers, those in the north of the country, and poor households were more likely to report improved conditions than others.

These results suggest that there is a strong link between market-oriented policies and cotton expansion on the one hand and the living conditions of farmers in Benin on the other hand. The analysis presented in this paper will further examine this link, focusing on the impact of changes in cotton prices on rural income and poverty.

3 Methods

The data used in this paper come from the *Equate des Petites Agricultures* (EPP) or Small Farmer Survey, carried out in 1998 by the International Food Policy Research Institute (IFPRI) and the *Laboratoire d'Analyse Régionale et d'Expertise Sociale* (LARES). The survey instrument consisted of a 24-page questionnaire, divided into 16 sections⁵. The households were selected using a two-stage stratified random sample procedure based on the 1997 Pre-Census of Agriculture. In each of the six departments⁶, villages were randomly selected, with the number of villages proportional to the volume of agricultural production, subject to a minimum of 10 villages per department. In total, one hundred villages were selected. In each village, nine households were randomly selected using lists prepared for the pre-Census of Agriculture. In a few villages, the number of interviewed households was eight or ten, resulting in a final sample size of 899 agricultural households. Sampling weights are used in calculating the results presented here. The survey was carried out from August to November 1998 (see IFPRI, 2000 for more detail).

The first objective, to describe living conditions and poverty among cotton growers and other farmers, is based on descriptive statistics from the EPP. In this analysis, we use per capita expenditure as our measure of poverty and well-being, and as a proxy for income. Per capita expenditure is calculated as

⁵ The 16 sections were Household characteristics, Housing characteristics, Land, Agricultural production, Labor use, Input use, Changes regarding input use, Credit, Crop marketing, Storage, Sources of information, Food and non-food consumption, Allocation of time, Asset ownership, Sources of income, and Perceptions of farmers.

 $^{^{6}}$ Since this study was carried out, an administrative reorganization has resulted in an increase in the number of departments from 6 to 12. The analysis in this report retains the old definitions of departments because this was the basis for the sampling design of the survey.

cash expenditure on consumption goods, the imputed value of home-produced food, and the rental equivalent of owner-occupied housing⁷.

In order to describe poverty, we must adopt a poverty line. One commonly-used international standard is US\$ 1 per person per day. Although this poverty line has the advantage of being internationally comparable, it results in a very high estimate of the incidence of poverty in Benin. According to the EPP, 95 percent of rural households in Benin live below this poverty line. Alternatively, we could adopt the poverty line identified by the 1994 *Enquête sur les Conditions de Vie en Milieu Rural* (ECVR). After adjusting for inflation between 1994 and 1998, the poverty line is 79,155 FCFA/adult equivalent, resulting in a rural poverty rate of just 21 percent⁸. This poverty line appears to define poverty too narrowly for our purposes. Since the main objective of this analysis is to compare the incidence and severity of poverty before and after a simulated reduction in world prices of cotton, we adopt a *relative* poverty line, set at the 40th percentile of per capita consumption expenditure.

The second objective is to estimate the short-run direct impact of lower cotton prices. The shortrun direct impact refers to impact on cotton farmers in the first year, before they have an opportunity to change their decisions regarding input use and crop mix. We simulate the impact of various percentage reductions in cotton prices on the incomes of rural households. In particular, the per capita income of household i after the price change can be calculated as follows:

$$y_{1i} = y_{0i} + (Q_{ci}\Delta P_{c}) / H_{i}$$
(1)

where y_{1i} is per capita income⁹ of household i after the shock, y_{0i} is per capita income before the shock, Q_c is the quantity of cotton produced by household i, P_c is the change in the price of cotton, and H_i is the number of members in household i. If a household does not grow cotton, then $Q_{ci}=0$ and the direct effect of lower cotton prices is zero ($y_{1i} = y_{0i}$). But if $Q_{ci} > 0$, then a price reduction ($P_c, < 0$) implies that income will fall ($y_{1i} = y_{0i}$).

The simulations are run with farm-level reductions in cotton price (P_c) of 10%, 20%, 30%, and 40%. The other variables (y_{oi} and Q_{ci}) are all defined at the household level, allowing the changes in per capita income to be calculated for each household in the sample. This "micro-simulation" approach

⁷ The advantages of expenditure over income as a measure of well-being are well-known: respondents are less likely to under-report expenditure, it is easier to measure when farming and other types of self-employment are widespread, and it varies less across seasons and from one year to the next, giving a better estimate of the long-run average standard of living.

⁸ The price level during the ECVR was taken to be the consumer price index (base December 1991) for August 1994, the mid-point of the ECVR data collection. The price level for the IFPRI-LARES Small Farmer Survey was assumed to be the price index for June 1998, the mid-point of the reference period for the survey. Thus, the ECVR poverty line of 56,500 FCFA/adult equivalent was increased by a factor of (200.2/142.9) = 1.40, yielding a 1998 poverty line of 79,155 FCFA/adult equivalent. See UNDP-MDR, 1996 and IFPRI, 2000 for more detail.

⁹ As mentioned above, we use per capita expenditure as a proxy for per capita income

allows us to estimate the change in income for any sub-group in rural areas, defined by income, farm-size, or other variables.

The impact of price changes on poverty is measured using the Foster-Greer-Thorbecke measures of poverty, defined as follows:

$$P_{\alpha} = \frac{1}{N} \sum_{i} \left[\frac{\mu - y_{i}}{\mu} \right]^{\alpha}$$
(2)

where P_a is the poverty measure, N is the number of households, is the poverty line, and y_i is the income or expenditure of poor household i (the summation occurs only over poor households). When =0, the poverty measure, P_0 , is the incidence of poverty, that is, the proportion of households whose income is below the poverty line. When =1, the poverty measure, P_1 , is the poverty-gap measure. The poverty gap is equal to the incidence of poverty multiplied by the average gap between the poverty line and the income of a poor household, expressed as a percentage of the poverty line. Thus, it takes into account the depth of poverty as well as the percentage of the households that are poor. If =2, then the poverty measure, P_2 , is called the poverty gap squared and it takes into account the degree of inequality among poor households, as well as the depth of poverty and the number of poor households (see Foster, Greer, and Thorbecke, 1984).

The third objective, to estimate the long-run, direct impact of lower cotton prices. Since this analysis takes into account the fact that farmers will substitute away from cotton and reduce input use, the long-run direct impact is smaller (in absolute terms) than the short-run direct impact of the change in cotton prices. One approach would be to sum the welfare effect of the change in cotton price and those associated with price changes in other markets (such as those for inputs and competing crops). Just et al (1982) show that the impact can also be measured by focusing exclusively on the original (cotton) market, but using general equilibrium elasticities that take into account the feed-back effect of other markets on cotton markets. In this analysis, we adopt the second approach. In particular, we use the following equation to describe the welfare impact of the change in cotton price:

$$y_{1i} = y_{0i} + (Q_{ci}\Delta P_{c}) / H_{i} + \left(\frac{1}{2}(\Delta P_{c})^{2} \varepsilon_{c} \frac{Q_{ci}}{P_{c}}\right) / H_{i}$$
(3)

where $_{c}$ is the general equilibrium supply elasticity of cotton and Pc is the price of cotton. Note that the second term is positive regardless of whether the price change is positive or negative. This implies that the long-term welfare effect of an increase (decrease) in price is more positive (less negative) than the short-term effect (see Minot and Goletti, 2000 for derivation).

In the absence of estimated elasticities of supply for cotton in Benin, we use a range of plausible elasticities to calculate the range of plausible welfare impacts. The elasticities used are 0.5, 1.0, and 1.5.

As in the analysis of the short-run effect, we simulate the impact of these changes on the income of each household in the sample (micro-simulation) in order to estimate the impact on different types of households in terms of income and poverty.

The fourth objective is to estimate the *total* impact of lower cotton prices. This analysis estimates the effect of lower cotton prices on both cotton farmers and other households. We focus on two types of indirect effects. First, the reduced income of cotton farmers implies reduced demand for consumer goods and services produced by other households and firms in the economy. We estimate this indirect effect by calculating the multiplier associated with consumer spending by cotton farmers. The multiplier is calculated based on the marginal propensity of cotton farmers to consume tradable goods. This marginal propensity to consume tradable goods is, in turn, calculated from the expenditure data in the IFPRI-LARES Small Farmer Survey and some assumptions about the tradability of the 33 expenditure categories in the survey.

The second type of indirect effect on households outside the cotton sector is the reduced demand for labor. Cotton is more labor-intensive than many other crops, so a reduction in cotton area is expected to reduce the demand for agricultural labor, thus reducing the wage income of households that depend on agricultural labor. We use data from the EPP to assess the magnitude of the change in demand for agricultural labor associated with reduced cotton output.

4 Characteristics of farmers in Benin

Before estimating the impact of changing cotton prices on rural households, it is useful to provide some background on the agricultural economy of Benin and the role of cotton. This provides some context for understanding and interpreting the results presented later.

According to the IFPRI-LARES Small Farmer Survey, the most widely grown crop in Benin is maize, cultivated by 89 percent of the farm households (see Table 3). Cowpeas are grown by almost half the farms, and manioc, yams, sorghum/millet, and cotton are each grown by roughly one third of the farm households.

Although cotton is grown by barely one third of the farmers in Benin, it plays an important part of the rural economy. If we average across all farmers, the average cotton area is 0.79 hectares and the average gross value of cotton production is 193,000 FCFA per farm. These figures imply that cotton accounts for about 18 percent of the area planted by farm households and 22 percent of the gross value of crop production. This makes cotton the second most important crop in value terms.

If we focus on the averages among cotton farmers, the average area planted with cotton is 2.32 hectares, producing 2.67 tons of seed cotton¹⁰. The value of this output is 568,000 FCFA (or US\$ 901) per cotton farm¹¹.

Another measure of the importance of cotton in the rural economy is its contribution to cash income. Benin farmers are quite market oriented, selling over half the output of cowpeas, groundnuts, manioc, and sweet potatoes, and selling almost half of the output of the "staple" foodcrop, maize (see Table 4). Nonetheless, cotton accounts for about one-third of the value of crop sales carried out by farm households in Benin.

Who grows cotton and how do cotton farmers differ from other farmers in Benin? As mentioned earlier, cotton production is concentrated in the north and center of Benin. About two-thirds of the farmers in the large department of Borgou grow cotton, as do 37 percent of those in Atacora and 64 percent of those in the central department of Zou. By contrast, in the three departments in the south (Atlantique, Mono, and Ouémé), the percentage ranges from zero to 25 percent (see Table 5). If we divide the farm households into quintiles, the proportion of farmers growing cotton does not seem to vary consistently across quintiles. If anything, the proportion of cotton growers is lower (28 percent) in the richest quintile (see Table 6).

Cotton growers tend to have farms that are, on average, twice as large as those of non-growers (5.3 hectares compared to 2.3 hectares). Based on this fact alone, one might expect cotton growers to be better off than non-growers. Nonetheless, cotton growers are similar to other farmers in terms of various measures of well-being. The incidence of poverty rate is slightly lower among cotton farmers (37 percent) than among other farmers (42 percent), but the per capita expenditure of cotton growers is about 8 lower than that of others, and the budget share allocated to food is almost identical to that of non-growers (see Table 7). The reason that the larger farms do not translate into a higher standard of living is that cotton growers are concentrated in the more arid north, where the agricultural potential is lower and where opportunities for non-farm employment are more scarce.

As mentioned in Section 2, there are sharp differences across regions in Benin. As shown in Table 8, the northern department of Atacora has the lowest average expenditure, the highest poverty rate, and the highest food share. In contrast, the coastal department of Atlantique (which includes the largest city) has the highest expenditure, the lowest poverty rate. Farmers in Borgou and Zou produce more than

¹⁰ It is worth noting that the average yield is calculated at the household level and aggregated, so it is not necessarily equal to the average quantity divided by the average area. A similar qualification applies to production, price, and value of output.
¹¹ When the Small Farmer Survey was carried out, the exchange rate was around 630 FCFA/US\$, so that the value

¹¹ When the Small Farmer Survey was carried out, the exchange rate was around 630 FCFA/US\$, so that the value of cotton production was US\$ 901 per cotton farm.

1.8 tons of cotton per household, compared to less than 500 kg per household in Atacora and even less on the three coastal departments.

5 Direct impact of lower cotton prices

In this section, we use the data from the IFPRI-LARES Small Farmer Survey to estimate the *direct* impact of lower cotton prices in Benin. The direct impact refers to the effect of the cotton price changes on Benin cotton farmers. First, we examine the impact of lower prices on the income and poverty of cotton farmers in the short-run, before they have an opportunity to respond to the lower prices. Next, we estimate the impact on cotton farmers in the longer run, after they have responded to the shock.

5.1 Short-term impact

As described in Section 3, we estimate the short-term change in income associated with lower cotton prices using household-level information on per capita expenditures and the volume of cotton production, combined with different assumptions about the reduction in cotton price. The results of these calculations are shown in Table 10. A 40 percent reduction in the farmgate price of cotton reduces the income of cotton growers from 99,437 FCFA/person to 78,730 FCFA/person, a reduction of 21 percent. Taking into account the incomes of non-growers, which do not change in this simulation, the average income falls from 105,203 FCFA/person to 97,944 FCFA/person., or 7 percent. Smaller reductions in the cotton price cause roughly proportionate changes in income (see Figure 2)..

With a 40 percent fall in the cotton price, the incidence of poverty (P_0) among cotton farmers rises from 37 percent to 59 percent. The average incidence of poverty, including both cotton growers and other farmers rises 8 percentage points, from 40 percent to 48 percent. In absolute terms, this implies that about 334 thousand people would fall below the poverty line as a result of a 40 percent reduction in cotton prices¹² (see

A 40 percent decrease in the price of cotton results in a doubling of the poverty gap (P_1) among cotton farmers, from 0.10 to 0.20, and a 40% increase in the poverty gap for all farm households in Benin. The poverty gap squared (P_2) or severity of poverty increases almost three-fold among cotton farmers and by 61 percent across all farm households.

This analysis can be broken down by department to evaluate regional differences in the impact of falling cotton prices¹³ (see Table 11 and Figure 4). In Atlantique and Ouémé, the reduction in cotton

¹² This estimate is obtained by multiplying the percentage point increase in poverty (.08), the number of farm households in Benin based on the sum of the sampling weights (474,964), and the average household size of farms in Benin according to the survey (8.8).

¹³ As mentioned earlier, since the survey was carried out, the number of departments has increased from 6 to 12. The sample size of the survey is too small to allow disaggregation of results by the newly defined departments.

prices has negligible effects on income and poverty because there are virtually no cotton farmers in these departments. On the other hand, the impact on the departments of Borgou and Zou are large. In Zou, a 40 percent reduction in cotton prices results a 15 percent fall in per capita income and a 17 percentage point increase in the incidence of poverty. In Borgou, the same decrease in cotton prices causes an 18 percent reduction in per capita income and a 18 percentage point increase in the incidence of poverty. In fact, the department of Borgou moves from having an "average" poverty rate (greater than in two departments and less than in two others) to having the highest incidence of poverty, 62 percent. Similarly, the poverty-gap (P_1) in Borgou increases by a factor of three and the severity of poverty (P_2) doubles as a result of the 40 percent reduction in cotton prices.

Similarly, we can examine the impact of reductions in cotton prices on different income categories (see Table 12 and Figure 5). The absolute reductions in income are greater for the high-income households, but all income categories show similar percentage reductions in per capita income as a result of a 40 percent decrease in cotton prices. By definition, all the households in the bottom two quintiles are poor so the incidence of poverty (P0) is 100 percent. However, the analysis indicates that about 30 percent of those households in the third quintile and 8 percent of those in the fourth quintile drop below the poverty line as a result of the 40 percent decrease in cotton prices.

Although the incidence of poverty in the bottom two quintiles cannot rise above 100 percent, the poverty gap measure (P1) and the severity of poverty (P2) can and do increase. In particular, a 40 percent drop in cotton prices causes the depth of poverty to rise from 0.38 to 0.43 and the severity of poverty to increase from 0.16 to 0.20.

Finally, we look at the effect of falling cotton prices on the cumulative distribution of income per capita (see Figure 6). Among other things, it gives us information about the sensitivity of the results to alternative poverty lines, an important consideration given that our poverty lines is relative (set at the 40th percentile in the base distribution). The point where the cumulative distribution cross the poverty line is the poverty rate (note that the base distribution cross the poverty line at the 40th percentile). It is clear from the graph that similar results would have been obtained for higher and lower poverty lines. It also shows graphically that a 40 percent reduction in cotton prices has roughly twice the effect of a 20 percent reduction.

5.2 Long-term impact

In the previous section, the welfare impact of cotton price decreases was calculated assuming that cotton farmers do not adjust their production patterns. While this is valid for estimating the short-run impact (less than one year), it is not realistic in the longer run (more than one year). In response to lower cotton prices, farmers will reallocate their land, labor, and other inputs to other crops and perhaps to

livestock and non-farm activities. The income level of farmers after this adjustment is generally higher than before adjustment (otherwise, they would not adjust), but lower than before the price shock (otherwise, they would have adopted the new crop mix even without the price shock). The greater the price-responsiveness of cotton farmers, the less the long-run adverse impact of the cotton price decrease.

Because of uncertainty regarding the supply elasticity of $\cot ton^{14}$, we carry out this analysis using three elasticities: 0.5, 1.0, and 1.5. In order to simplify the discussion, we present only the impact of a 40 percent reduction in cotton prices. These results are presented with the base levels and with the short-run impact. Since the assumption behind the short-run impact is that the supply elasticity is zero (=0)., they are labeled as such.

As described in Section 5.1, the short-run impact of the lower cotton price is to reduce average per capita income from 105,203 FCFA to 97,944 FCFA, or 7 percent. If the general equilibrium supply elasticity of cotton is 0.5, the average income is 98,670 FCFA/person, a decline of 6 percent from the base. At the other extreme, if the supply elasticity is 1.5, then the average income is 100,122 FCFA/person, a reduction of 5 percent from the base (see Table 13).

In the long run, a reduction of 40 percent in the price of cotton is associated with a 20-21 percentage point increase in the incidence of poverty among cotton growers and a 6-7 percentage point increase in the overall rural poverty rate, depending on the assumption regarding the supply elasticity. The depth of poverty (P_1) rises from 0.10 to 0.12 - 0.13, again depending on the elasticity assumption. And the severity of poverty (P_2) increases from 0.036 to 0.047 - 0.058 (see Table 13). As expected, the long-run impact of the 40 percent reduction in cotton prices is somewhat less adverse than the short-run impact. It is notable, however, that the results are not very sensitive to the elasticity assumption.

The long-run effects on each department are given in Table 14. For example, in Borgou, per capita income falls 18 percent (from 94,803 FCFA to 77,409 FCFA) in the short-run, but rebounds 4 percentage points (to 80,888 FCFA) if the supply elasticity is 1.0 and 7 percentage points (to 82,627 FCFA) if the elasticity is 1.5. Similarly, the per capita income in Zou falls 15 percent in the short-run, but rebounds 3 percentage points in the long-run if the elasticity is 1.0.

The poverty rates in each department follow the same pattern in reverse. In the short-run, they rise as a result of the 40 percent fall in cotton prices, but in the long-run they fall back down part of the way. In Borgou, the poverty rate rises from 44 percent to 62 percent in the short run, falling back to 58-60 percent in the long run, depending on which elasticity assumption is used. Similarly, the incidence of poverty in Zou increases from 33 percent to 50 percent in the short run, then falls to 47-49 percent in the

¹⁴ Estimates of the supply elasticity of cotton in Benin are not available, but two studies have estimated the supply elasticity of cotton in Tanzania. Dercon (1993) estimated a supply elasticity of 0.63, while Delgado and Minot (2000), using more recent data, obtained an estimate of 1.0.

long run. As described above, there is little or no change in poverty in the three southern departments (Atlantique, Mono, and Ouémé) because there are very few cotton growers in these departments.

Looking at the patterns by expenditure category, we see similar patterns (see Table 15). Among the poorest 20 percent of farm households, the 40 percent fall in cotton price results in a 7 percent decline in income in the short-run, followed by a 1-2 percent rebound in the long run as households respond to the new price. Among the richest 20 percent, income initially falls 5 percent, before going back up 0.5-1.5 percent.

The incidence of poverty among the bottom two expenditure groups cannot increase (it is already 100 percent), but the other poverty measures (P_1 and P_2) follow the expected pattern of rising and then falling part-way back. As noted earlier, 30 percent of those in the middle expenditure group fall into poverty in the short run as a result of the falling cotton price, but in the long run 1-4 percent of the group rises back out of poverty.

In Figure 7, we show the cumulative distribution of income in the base scenario, with a 40 percent reduction in cotton prices in the short run (=0), and with a 40 percent reduction in cotton prices in the long run (=1.5). Although the long-run supply elasticity used in this figure is at the upper end of what we believe is plausible, the difference between the short-run and long-run results is not very large. In other words, the long-term results are not very sensitive to the assumption regarding the supply elasticity of cotton. Even with a relatively elastic supply (=1.5), the response of farmers only offsets about one-third of the initial negative short-run impact.

6 Indirect impact of lower cotton prices

In Section 6, we described the long-run *direct* impact of falling cotton prices on farmers in Benin. The analysis was based on the impact of lower prices on the incomes of cotton farmers themselves, after they respond to the lower price but excluding any indirect effects on farmers who do not grow cotton. Although a general equilibrium analysis is beyond the scope of this paper, we examine two types of indirect effects. First, since the income of cotton farmers declines, their spending on other goods and services declines, leading to reduced prices of non-tradable goods and reduced income for household that produce them. We use data on the composition of spending by cotton farmers to estimate the multiplier effect of lower spending by cotton growers. Second, as cotton farmers scale back cotton production in response to the lower prices, they also reduce the demand for agricultural labor. This has indirect effect on households that earn income from agricultural labor.

6.1 Impact of lower cotton prices on other sectors

The direct effect of lower cotton prices is on cotton farmers, but other households are affected indirectly. As cotton farmers reduce their spending, the demand for other goods and services contracts, affecting the incomes of households that produce those goods and services and, in turn, their spending patterns. A complete analysis of these effects would require a computable general equilibrium model, for which parameter estimates are not available. In contrast, multiplier analysis uses a simplifying assumption to obtain an approximation based on data that are available. Multiplier analysis assumes that prices are fixed and that production and income are constrained only by demand. Under these assumptions the total (direct and indirect) impact of an exogenous shock to demand, is affected by the composition of demand between tradable and non-tradable goods and services. In particular, the total effect is $1/(1-MPC_n)$ where MPC_n is the marginal propensity to consume non-tradables (see Delgado et al, 1999). In the extreme, if cotton growers buy all imported or tradable goods ($MPC_n = 0$), then the decline in cotton prices will have no effect on domestic incomes. If, on the other hand, cotton growers buy primarily non-tradable goods, then the reduction in cotton prices will have a large multiplier effect within the country.

This section estimates the multiplier effect associated with changes in income of cotton growers. In particular, a regression analysis is used to estimate the marginal propensity to consume tradable goods. We begin by making some assumptions about the tradability of goods and services. For this study, the following goods were considered non-tradable: maize, sorghum, beans, cassava, cassava flour (*gari*), yams, potatoes and other tubers, vegetables, fruit, meat, fish, eggs, dairy products, meals consumed outside the home, home repairs or expansion, school-related expenses, medical service fees, and expenses for funerals, marriages, or religious causes. Tradable goods included most manufactured goods and some food products such as rice, groundnuts, salt, sugar, and drinks.

The marginal propensity to consume tradables is estimated using household-level data from the EPP, regressing tradable goods per capita against per capital expenditure, household size, the sex of the household head, the percent of children under the age of 15, and the percent of adults over the age of 65 years. Table 16 shows the results of the regression analysis for cotton growers. The coefficient on per capita expenditure is 0.366, implying that for every additional dollar that cotton growers spend, 36.6% is allocated to tradable goods and services. This is somewhat higher than the share of tradable goods in the budgets of cotton farmers (.323), implying that the income elasticity of tradable goods and services is somewhat greater than unity (1.13).

The multiplier associated with the spending patterns of cotton farmers is 2.7 (1/.366). In other words, for every dollar change in spending by cotton farmers, there is a total change in spending of 2.7 dollars^{15} .

6.2 Impact of lower cotton prices on labor demand

As the price of cotton falls, farmers can be expected to shift their resources away from cotton into other crops, livestock, or non-farm activities. The impact of this substitution depends on the labor intensity of cotton production relative to that of the alternative crops or activities. If cotton is more labor intensive than the substitution away from cotton will reduce the demand for labor and adversely affect the income of households that depend on wage labor. According to the EPP, the poorest quintile of Benin farmers earn 14 percent of their income from wages, compared to 7 percent among the richest quintile. We can address this question in two ways: by examining the labor intensity of cotton compared to other crops and by estimating demand for hired labor as a function of various explanatory factors including cotton production.

Regarding the labor intensity of cotton, Table 17 shows that 21 percent of all labor hired by agricultural households is used for cotton. By comparison, cotton accounts for 18 percent of the area planted by Benin farmers. This implies that, on a per hectare basis, cotton is about 20 percent more labor intensive than other crops. Furthermore, if we assume that the labor intensity doesn't change, a 50 percent reduction in cotton area would result in a reduction in demand for hired labor in Benin of roughly 2 percent¹⁶. If labor markets are geographically segmented, the proportional effect would of course be larger within the cotton growing areas but smaller outside these areas.

The alternative approach is to use regression analysis to examine the impact of changes in cotton production on demand for hired labor. In the absence of time-series data, we are forced to rely on cross-section data from the EPP to examine this relationship. We assumes that this cross-sectional relationship can be applied to the impact of changes in cotton output on demand for hired labor. The dependent variable is the number of person-days of hired agricultural labor used by households. We restrict the sample to survey clusters in which at least one household grows cotton. The purpose of this is to exclude agro-ecological zones that are entirely different (and thus may be affected by other variables such as crop

¹⁵ This analysis was repeated for different household groups to examine variations in the multiplier effect across the six (former) departments and across expenditure quintiles. The results did not show any distinct pattern. Within the department of Borgou, the multiplier for non-cotton growers was quite large, 8.06, compared to the other departments where the multiplier ranged from 2.19 to 4.08. Within the income quintiles, the multiplier rose slightly from the poorest quintile the third quintile and then decreased among the fourth and wealthiest quintiles for both cotton and non-cotton growers.

¹⁶ Cotton accounts for 21 percent of the labor demand, so a 50 percent reduction in cotton output would displace 10.5 percent of the hired labor. All but 20 percent would be employed on substitute crops, implying a net loss of about 2 percent.

mix and population density) without necessarily excluding households that do not grow cotton. The independent variables are per capita expenditure of the household (a proxy for the opportunity cost of family labor), the size of the household (an indicator of the availability of family labor), farm size (which influences the marginal product of labor), the quantity of cotton grown, the quantity of cotton squared, and the village-level average wage paid to agricultural laborers.

As shown in Table 18, the regression results indicate that the demand for hired labor is, as expected, positively associated with per capita expenditure of the household, positively related to farm size, and negatively related to the village-level average wage rate. The effect of cotton production on the demand for hired labor, however, is statistically insignificant, as is the squared cotton term. This suggests that, other things being equal, farms growing less cotton do not use any less hired labor.

Two qualifications need to be made about this conclusions. First, cotton production is clearly a choice variable and hence not exogenous. Crop decisions may be jointly decided along with labor hiring decisions. Second, the analysis focuses on crop substitution, ignoring possible substitution of land and labor toward livestock production or non-farm activities. Nonetheless, we do not find evidence that substitution away from cotton toward other crops will have a significant effect on labor demand and hence the livelihood of households that depend on wage income.

7 Conclusions

This paper analyzes the impact of changes in world cotton prices on farmers in Benin. Both quantitative measures of per capita expenditure from household surveys and qualitative responses to a nationally representative survey suggest that rural living conditions improved over the 1990s. Furthermore, farmers tend to attribute this improvement in rural living conditions to economic factors such as crop prices, availability of food, and access to non-farm employment. Although the causal link is difficult to establish with certainty, it appears the economic reforms of the 1990s (including the 1994 devaluation) and the growth of cotton production during this period contributed to the improvement in rural standards of living.

The link between cotton markets and rural living conditions can, however, work against farmers as well. The analysis in this paper is motivated by the recent 39 percent decline in the world price of cotton. We combine farm survey data from 1998 with assumptions about the decline in farm-level prices to estimate the short- and long-term direct effects of cotton price reductions on rural income and various measures of poverty. We also use the survey data to study two types of indirect effects: the impact of lower incomes of cotton farmers on other households through the consumption multiplier and the impact on the demand for agricultural labor by cotton growers.

The results indicate that there is a strong link between cotton prices and rural welfare in Benin. A 40 percent reduction in farm-level prices of cotton is likely to result in a reduction in rural per capita income of 7 percent in the short-run and 5-6 percent in the long-run. Furthermore, poverty rises 8 percentage points in the short-run, equivalent to an increase of 334 thousand in the number of individuals in families below the poverty line. In the long run, as household adjust to the new prices, the poverty rate settles down somewhat, remaining 6-7 percentage points higher than originally.

In order to explore the magnitude of the indirect effects of lower cotton prices, we estimate econometrically the marginal propensity to consume tradable goods. According to this analysis, for every additional dollar of income, cotton growers spend about 37 percent on tradable goods and the remaining 63 percent on non-tradable goods. Thus, a crude estimate of the multiplier is 2.7, meaning that one dollar of reduced spending by cotton growers results in a contraction of 2.7 dollars in overall demand.

We also examine the potential effect of a reduction in cotton production on the demand for hired labor and hence the income of households that depend on wage income. We do not find evidence of a strong adverse effect of reduced cotton production on demand hired agricultural labor. First, cotton accounts for 21 percent of hired labor demand and 18 percent of planted area, indicating that it is only slightly more labor intensive than other crops. Second, regression analysis to estimate the farm-level demand for hired agricultural labor identifies a number of significant coefficients with expected signs, but there was no statistically significant link between cotton production and demand for hired labor. More information on the degree of segmentation of labor markets and on the possibility of substitution into livestock and other non-crop activities would be needed, however, to answer this question more definitively.

Overall, the results in this paper challenge the stereotype of the rural populations in developing countries as consisting of subsistence farmers that are relatively unconnected to, and thus unaffected, by swings in world commodity markets. At least in the case of Benin, fluctuations in world cotton prices have a significant effect on rural incomes and poverty. Furthermore, to the extent that policies to subsidize farmers in the United States and elsewhere tend to dampen world prices, efforts to reduce agricultural protection in these markets would reduce poverty in Benin and other poor cotton exporting countries.

FIGURES

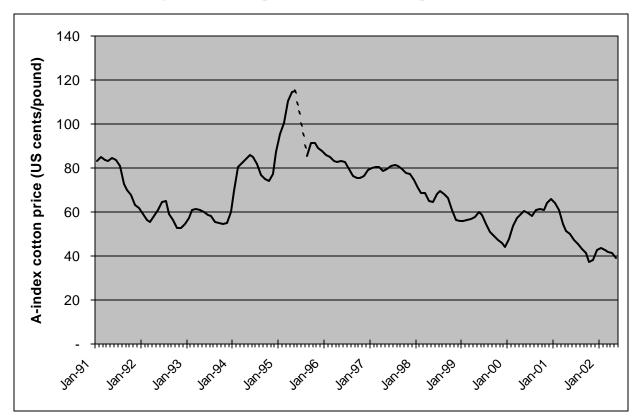

Figure 1. Cotton prices in Northern Europe (A-Index)

Source: USDA, 2002; USDA, 2001.

Note: The A-Index is the average of the five lowest prices of cotton in Northern European markets for middling 1 3/32 inch fiber length. For June and July 1995, there was no A-Index quotation; the dotted line represents a simple linear interpolation.

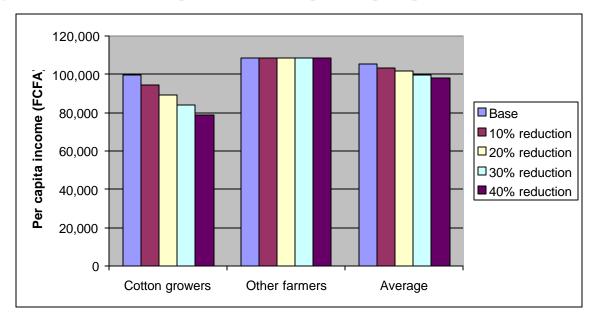

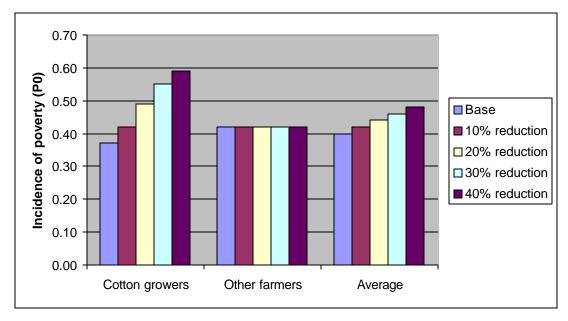

Figure 2. Short-run direct impact of lower cotton prices on per capita income
