

WHEN THE CRAMÉR-RAO INEQUALITY PROVIDES NO INFORMATION

STEVEN J. MILLER

ABSTRACT. We investigate a one-parameter family of probability densities (related to the Pareto distribution, which describes many natural phenomena) where the Cramér-Rao Inequality provides no information.

1. CRAMÉR-RAO INEQUALITY

Cramér-Rao Inequality: *Let $f(x; \theta)$ be a probability density function with continuous parameter θ . Let X_1, \dots, X_n be independent random variables with density $f(x; \theta)$, and let $\hat{\Theta}(X_1, \dots, X_n)$ be an unbiased estimator of θ . Assume that $f(x; \theta)$ satisfies two conditions:*

(1) *we have*

$$\frac{\partial}{\partial \theta} \left[\int \cdots \int \hat{\Theta}(x_1, \dots, x_n) \prod_{i=1}^n f(x_i; \theta) dx_i \right] = \int \cdots \int \hat{\Theta}(x_1, \dots, x_n) \frac{\partial \prod_{i=1}^n f(x_i; \theta)}{\partial \theta} dx_1 \cdots dx_n; \quad (1.1)$$

(2) *for each θ , the variance of $\hat{\Theta}(X_1, \dots, X_n)$ is finite.*

Then

$$\text{var}(\hat{\Theta}) \geq \frac{1}{n \mathbb{E} \left[\left(\frac{\partial \log f(x; \theta)}{\partial \theta} \right)^2 \right]}, \quad (1.2)$$

where \mathbb{E} denotes the expected value with respect to the probability density function $f(x; \theta)$.

For a proof, see for example [CaBe]. The expected value in (1.2) is called the *information number* or the *Fisher information* of the sample.

Key words and phrases. Cramér-Rao Inequality, Pareto distribution, power law.

As variances are non-negative, the Cramér-Rao inequality (equation (1.2)) provides no useful bounds on the variance of an unbiased estimator if the information is infinite, as in this case we obtain the trivial bound that the variance is greater than or equal to zero. We find a simple one-parameter family of probability density functions (related to the Pareto distribution) that satisfy the conditions of the Cramér-Rao inequality, but the expectation (i.e., the information) is infinite. Explicitly, our main result is

Theorem: *Let*

$$f(x; \theta) = \begin{cases} a_\theta \frac{1}{x^\theta \log^3 x} & \text{if } x \geq e \\ 0 & \text{otherwise,} \end{cases} \quad (1.3)$$

where a_θ is chosen so that $f(x; \theta)$ is a probability density function. The information is infinite when $\theta = 1$. Equivalently, the Cramér-Rao inequality yields the trivial (and useless) bound that $\text{Var}(\hat{\Theta}) \geq 0$ for any unbiased estimator $\hat{\Theta}$ of θ when $\theta = 1$.

In §2 we analyze the density in our theorem in great detail, deriving needed results about a_θ and its derivatives as well as discussing how $f(x; \theta)$ is related to important distributions used to model many natural phenomena. We show the information is infinite when $\theta = 1$ in §3, which proves our theorem.

2. AN ALMOST PARETO DENSITY

Consider

$$f(x; \theta) = \begin{cases} a_\theta \frac{1}{x^\theta \log^3 x} & \text{if } x \geq e \\ 0 & \text{otherwise,} \end{cases} \quad (2.1)$$

where a_θ is chosen so that $f(x; \theta)$ is a probability density function. Thus

$$\int_e^\infty a_\theta \frac{dx}{x^\theta \log^3 x} = 1. \quad (2.2)$$

We chose to have $\log^3 x$ in the denominator to ensure that the above integral converges, as does $\log x$ times the integrand; however, the expected value (in the expectation in (1.2)) will not converge.

For example, $1/x \log x$ diverges (its integral looks like $\log \log x$) but $1/x \log^2 x$ converges (its integral looks like $1/\log x$); see pages 62–63 of [Rud] for more on close sequences where one converges but the other does not. This distribution is close to the Pareto distribution (or a power law). Pareto distributions are very useful in describing many natural phenomena; see for example [DM, Ne, NM]. The inclusion of the factor of $\log^{-3} x$ allows us to have the exponent of x in the density function equal 1 *and have the density function defined for arbitrarily large x* ; it is also needed in order to apply the Dominated Convergence Theorem to justify some of the arguments below. If we remove the logarithmic factors, then we obtain a probability distribution only if the density vanishes for large x . As $\log^3 x$ is a very slowly varying function, our distribution $f(x; \theta)$ may be of use in modeling data from an unbounded distribution where one wants to allow a power law with exponent 1, but cannot as the resulting probability integral would diverge. Such a situation occurs frequently in the Benford Law literature; see [Hi, Rai] for more details.

We study the variance bounds for unbiased estimators $\hat{\Theta}$ of θ , and in particular we show that when $\theta = 1$ then the Cramér-Rao inequality yields a useless bound.

Note that it is not uncommon for the variance of an unbiased estimator to depend on the value of the parameter being estimated. For example, consider the uniform distribution on $[0, \theta]$. Let \bar{X} denote the sample mean of n independent observations, and $Y_n = \max_{1 \leq i \leq n} X_i$ be the largest observation. The expected value of $2\bar{X}$ and $\frac{n+1}{n}Y_n$ are both θ (implying each is an unbiased estimator for θ); however, $\text{Var}(2\bar{X}) = \theta^2/3n$ and $\text{Var}(\frac{n+1}{n}Y_n) = \theta^2/n(n+1)$ both depend on θ , the parameter being estimated (see, for example, page 324 of [MM] for these calculations).

Lemma 2.1. *As a function of $\theta \in [1, \infty)$, a_θ is a strictly increasing function and $a_1 = 2$. It has a one-sided derivative at $\theta = 1$, and $\frac{da_\theta}{d\theta} \in (0, \infty)$.*

Proof. We have

$$a_\theta \int_e^\infty \frac{dx}{x^\theta \log^3 x} = 1. \quad (2.3)$$

When $\theta = 1$ we have

$$a_1 = \left[\int_e^\infty \frac{dx}{x \log^3 x} \right]^{-1}, \quad (2.4)$$

which is clearly positive and finite. In fact, $a_1 = 2$ because the integral is

$$\int_e^\infty \frac{dx}{x \log^3 x} = \int_e^\infty \log^{-3} x \frac{d \log x}{dx} = \frac{-1}{2 \log^2 x} \Big|_e^\infty = \frac{1}{2}; \quad (2.5)$$

though all we need below is that a_1 is finite and non-zero, we have chosen to start integrating at e to make a_1 easy to compute.

It is clear that a_θ is strictly increasing with θ , as the integral in (2.4) is strictly decreasing with increasing θ (because the integrand is decreasing with increasing θ).

We are left with determining the one-sided derivative of a_θ at $\theta = 1$, as the derivative at any other point is handled similarly (but with easier convergence arguments). It is technically easier to study the derivative of $1/a_\theta$, as

$$\frac{d}{d\theta} \frac{1}{a_\theta} = -\frac{1}{a_\theta^2} \frac{da_\theta}{d\theta} \quad (2.6)$$

and

$$\frac{1}{a_\theta} = \int_e^\infty \frac{dx}{x^\theta \log^3 x}. \quad (2.7)$$

The reason we consider the derivative of $1/a_\theta$ is that this avoids having to take the derivative of the reciprocals of integrals. As a_1 is finite and non-zero, it is easy to pass to $\frac{da_\theta}{d\theta} \Big|_{\theta=1}$. Thus we have

$$\begin{aligned} \frac{d}{d\theta} \frac{1}{a_\theta} \Big|_{\theta=1} &= \lim_{h \rightarrow 0^+} \frac{1}{h} \left[\int_e^\infty \frac{dx}{x^{1+h} \log^3 x} - \int_e^\infty \frac{dx}{x \log^3 x} \right] \\ &= \lim_{h \rightarrow 0^+} \int_e^\infty \frac{1 - x^h}{h} \frac{1}{x^h} \frac{dx}{x \log^3 x}. \end{aligned} \quad (2.8)$$

We want to interchange the integration with respect to x and the limit with respect to h above. This interchange is permissible by the Dominated Convergence Theorem (see Appendix A for details of the justification).

Note

$$\lim_{h \rightarrow 0^+} \frac{1 - x^h}{h} \frac{1}{x^h} = -\log x; \quad (2.9)$$

one way to see this is to use the limit of a product is the product of the limits, and then use L'Hospital's rule, writing x^h as $e^{h \log x}$. Therefore

$$\left. \frac{d}{d\theta} \frac{1}{a_\theta} \right|_{\theta=1} = - \int_e^\infty \frac{dx}{x \log^2 x}; \quad (2.10)$$

as this is finite and non-zero, this completes the proof and shows $\left. \frac{da_\theta}{d\theta} \right|_{\theta=1} \in (0, \infty)$. \square

Remark 2.2. We see now why we chose $f(x; \theta) = a_\theta/x^\theta \log^3 x$ instead of $f(x; \theta) = a_\theta/x^\theta \log^2 x$. If we only had two factors of $\log x$ in the denominator, then the one-sided derivative of a_θ at $\theta = 1$ would be infinite.

Remark 2.3. Though the actual value of $\left. \frac{da_\theta}{d\theta} \right|_{\theta=1}$ does not matter, we can compute it quite easily. By (2.10) we have

$$\begin{aligned} \left. \frac{d}{d\theta} \frac{1}{a_\theta} \right|_{\theta=1} &= - \int_e^\infty \frac{dx}{x \log^2 x} \\ &= - \int_e^\infty \log^{-2} x \frac{d \log x}{dx} \\ &= \left. \frac{1}{\log x} \right|_e^\infty = -1. \end{aligned} \quad (2.11)$$

Thus by (2.6), and the fact that $a_1 = 2$ (Lemma 2.1), we have

$$\left. \frac{da_\theta}{d\theta} \right|_{\theta=1} = -a_1^2 \cdot \left. \frac{d}{d\theta} \frac{1}{a_\theta} \right|_{\theta=1} = 4. \quad (2.12)$$

3. COMPUTING THE INFORMATION

We now compute the expected value, $\mathbb{E} \left[\left(\frac{\partial \log f(x; \theta)}{\partial \theta} \right)^2 \right]$; showing it is infinite when $\theta = 1$ completes the proof of our main result. Note

$$\begin{aligned} \log f(x; \theta) &= \log a_\theta - \theta \log x + \log \log^{-3} x \\ \frac{\partial \log f(x; \theta)}{\partial \theta} &= \frac{1}{a_\theta} \frac{da_\theta}{d\theta} - \log x. \end{aligned} \quad (3.1)$$

By Lemma 2.1 we know that $\frac{da_\theta}{d\theta}$ is finite for each $\theta \geq 1$. Thus

$$\begin{aligned} \mathbb{E} \left[\left(\frac{\partial \log f(x; \theta)}{\partial \theta} \right)^2 \right] &= \mathbb{E} \left[\left(\frac{1}{a_\theta} \frac{da_\theta}{d\theta} - \log x \right)^2 \right] \\ &= \int_e^\infty \left(\frac{1}{a_\theta} \frac{da_\theta}{d\theta} - \log x \right)^2 \cdot a_\theta \frac{dx}{x^\theta \log^3 x}. \end{aligned} \quad (3.2)$$

If $\theta > 1$ then the expectation is finite and non-zero. We are left with the interesting case when $\theta = 1$. As $\frac{da_\theta}{d\theta}|_{\theta=1}$ is finite and non-zero, for x sufficiently large (say $x \geq x_1$ for some x_1 , though by Remark 2.3 we see that we may take any $x_1 \geq e^4$) we have

$$\left| \frac{1}{a_1} \frac{da_\theta}{d\theta} \Big|_{\theta=1} \right| \leq \frac{\log x}{2}. \quad (3.3)$$

As $a_1 = 2$, we have

$$\begin{aligned} \mathbb{E} \left[\left(\frac{\partial \log f(x; \theta)}{\partial \theta} \right)^2 \right] \Big|_{\theta=1} &\geq \int_{x_1}^\infty \left(\frac{\log x}{2} \right)^2 a_1 \frac{dx}{x \log^3 x} \\ &= \int_{x_1}^\infty \frac{dx}{2x \log x} \\ &= \frac{1}{2} \int_{x_1}^\infty \log^{-1} x \frac{d \log x}{dx} \\ &= \frac{1}{2} \log \log x \Big|_{x_1}^\infty \\ &= \infty. \end{aligned} \quad (3.4)$$

Thus the expectation is infinite. Let $\hat{\Theta}$ be *any* unbiased estimator of θ . If $\theta = 1$ then the Cramér-Rao Inequality gives

$$\text{var}(\hat{\Theta}) \geq 0, \quad (3.5)$$

which provides no information as variances are always non-negative.

APPENDIX A. APPLYING THE DOMINATED CONVERGENCE THEOREM

We justify applying the Dominated Convergence Theorem in the proof of Lemma 2.1. See, for example, [SS] for the conditions and a proof of the Dominated Convergence Theorem.

Lemma A.1. *For each fixed $h > 0$ and any $x \geq e$, we have*

$$\left| \frac{1 - x^h}{h} \frac{1}{x^h} \right| \leq e \log x, \quad (\text{A.1})$$

and $\frac{e \log x}{x \log^3 x}$ is positive and integrable, and dominates each $\frac{1 - x^h}{h} \frac{1}{x^h} \frac{1}{x \log^3 x}$.

Proof. We first prove (A.1). As $x \geq e$ and $h > 0$, note $x^h \geq 1$. Consider the case of $1/h \leq \log x$.

Since $|1 - x^h| < 1 + x^h \leq 2x^h$, we have

$$\frac{|1 - x^h|}{hx^h} < \frac{2x^h}{hx^h} \leq \frac{2}{h} \leq 2 \log x. \quad (\text{A.2})$$

We are left with the case of $1/h > \log x$, or $h \log x < 1$. We have

$$\begin{aligned} |1 - x^h| &= |1 - e^{h \log x}| \\ &= \left| 1 - \sum_{n=0}^{\infty} \frac{(h \log x)^n}{n!} \right| \\ &= h \log x \sum_{n=1}^{\infty} \frac{(h \log x)^{n-1}}{n!} \\ &< h \log x \sum_{n=1}^{\infty} \frac{(h \log x)^{n-1}}{(n-1)!} = h \log x \cdot e^{h \log x}. \end{aligned} \quad (\text{A.3})$$

This, combined with $h \log x < 1$ and $x^h \geq 1$ yields

$$\frac{|1 - x^h|}{hx^h} < \frac{eh \log x}{h} = e \log x. \quad (\text{A.4})$$

It is clear that $\frac{\log x}{x \log^3 x}$ is positive and integrable, and by L'Hospital's rule (see (2.9)) we have that

$$\lim_{h \rightarrow 0^+} \frac{1 - x^h}{h} \frac{1}{x^h} \frac{1}{x \log^3 x} = -\frac{1}{x \log^2 x}. \quad (\text{A.5})$$

Thus the Dominated Convergence Theorem implies that

$$\lim_{h \rightarrow 0^+} \int_e^\infty \frac{1-x^h}{h} \frac{1}{x^h} \frac{dx}{x \log^3 x} = - \int_e^\infty \frac{dx}{x \log^2 x} = -1 \quad (\text{A.6})$$

(the last equality is derived in Remark 2.3). \square
