# Biases in First and Second Moments of the Fourier Coefficients in One- and Two-Parameter Families of Elliptic Curves

Jiefei (Michelle) Wu

Under the Supervision of Professor Steven J. Miller

November 2020

#### Abstract

Let  $\mathcal{E}: y^2 = x^3 + A(T)x + B(T)$  be a non-trivial one-parameter family of elliptic curves, and consider the  $k^{\text{th}}$  moments  $pA_{k,\mathcal{E}}(p) := \sum_{t \mod p} a_{\mathcal{E}_t}(p)^k$  of the Fourier coefficients  $a_{\mathcal{E}_t}(p) :=$  $p+1-|\mathcal{E}_t(\mathbb{F}_p)|$ . Rosen and Silverman proved that if  $\mathcal{E}$  is a rational surface then there is a negative bias in the first moment  $A_{1,\mathcal{E}}(p)$  (this is conjectured to hold for all elliptic surfaces); this bias is responsible for the rank of the elliptic surface. Michel investigated the second and higher moments; these are important as well and are related to the distribution of zeros of the L-function associated to the elliptic curve. He proved that  $pA_{2,\mathcal{E}}(p) = p^2 + O(p^{3/2})$ , with the lower order terms of size  $p^{3/2}$ , p,  $p^{1/2}$  and 1 having important cohomological interpretations. In his Ph.D. thesis, Miller proposed that there is also a bias in the second moment, and the largest lower-order coefficient that does not average to zero is on average negative. This was proven for many families by Mackall, Miller, Rapti, and Winsor, and explains some of the disagreements between theory and computations for the small conductors for the distribution of ranks in families of elliptic curves; reconciling this disparity is one of the most important questions in the subject (it is still an open question, for example, if the rank can be arbitrarily large). If the bias conjecture holds, then it helps to explain for small conductors why numerically on average the rank is higher than expected, which helps us to understand one of the million dollar Clay Millennium prizes - the Birch and Swinnerton-Dyer Conjecture - which states that the geometric rank of a rational elliptic surface equals to its analytic rank. In this paper, we explore the first and second moments of some one- and two-parameter families of elliptic curves, looking to see if the biases persist and exploring the consequence these have on fundamental properties of elliptic curves. We observe that in all of the one- and two-parameter families we proved theoretically that the first term that does not average to zero in the second-moment expansion of the Fourier coefficients has a negative average.

### 1 Introduction

#### 1.1 Rational Points on a Quadratic Equation

For thousands of years, there has been interest in finding integer solutions to equations or systems of equations with integer coefficients. These are called Diophantine equations. Perhaps the most famous is the Pythagorean theorem.

Lemma 1.1 (Pythagorean Theorem). If a, b, and c are the sides of a right triangle, then

$$a^2 + b^2 = c^2. (1.1)$$

However, it is not clear that there are any rational solutions. It distressed the Greeks that the right triangle with sides of integer length 1 and 1 has a hypotenuse of irrational length  $\sqrt{2}$ . Derived from the Pythagorean theorem, Pythagorean triples can generate right triangles with sides of integer lengths.

**Lemma 1.2** (Pythagorean Triples). Given any Pythagorean triple there exist m and n with m > n > 0 such that

$$a = k \cdot (m^2 - n^2), \ b = k \cdot (2mn), \ c = k \cdot (m^2 + n^2),$$
 (1.2)

where m, n and k are positive integers with m > n and m and n are coprime and not both odd; this can generate all Pythagorean Triples.

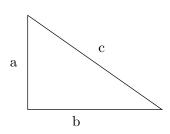

Figure 1: A right triangle with side length of a, b and c

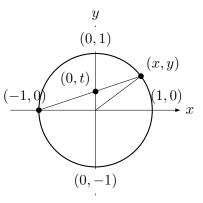

Figure 2: A rational parametrization of the circle  $x^2 + y^2 = 1$ 

Finding integer Pythagorean triples is equivalent to finding rational points on the unit circle  $x^2 + y^2 = 1$ ; just let

$$x = \frac{a}{c} \text{ and } y = \frac{b}{c}. \tag{1.3}$$

*Proof.* In Figure 2, we know one rational solution, (-1, 0). The line through (x, y) with slope t is given by the equation

$$y = t(1+x).$$
 (1.4)

Hence, the other point of intersection of the line with the unit circle is

$$1 - x^2 = y^2 = t^2 (1 + x)^2. (1.5)$$

Dividing each side by the root (1 + x), corresponding to the root x = -1, we get

$$1 - x = t^2 (1 + x). (1.6)$$

Using the above relation, we find

$$x = \frac{1-t^2}{1+t^2}, \ y = \frac{2t}{1+t^2}.$$
(1.7)

We see that if x and y are rational numbers, then the slope t = y/(1+x) is a rational number too. Conversely, if t is a rational number, then x and y are rational numbers too. Hence, by letting t range over the rational numbers numbers, we can generate all the rational pairs on the circle (except (-1, 0) as in this case t is infinite).

Since we are able to generate the rational points on a quadratic equation, it is natural for us to study how to generate the rational points on a cubic equation, such as an elliptic curve.

#### 1.2 Rational Points on a Cubic Equation

We show how to pass from quadratics to cubics by looking at some special number, namely right triangles with area 1. We have the following equation:

$$1 = \frac{1}{2}ab. \tag{1.8}$$

Next, we substitute a = xc and b = yc from (1.3),

$$1 = \frac{1}{2}c^2 xy. (1.9)$$

Then, we plug in our results from (1.7) and we obtain

$$1 = \frac{1}{2}c^{2}\left(\frac{1-t^{2}}{t^{2}+1}\right)\left(\frac{2t}{t^{2}+1}\right)$$
$$= \frac{c^{2}}{(t^{2}+1)^{2}}(t-t^{3}).$$
(1.10)

Divided both sides by  $c^2/(t^2+1)^2$ , we get

$$\left(\frac{t^2+1}{c}\right)^2 = t - t^3.$$
(1.11)

Let  $Y = (t^2 + 1)/c$  and X = -t. We have

$$Y^2 = X^3 - X, (1.12)$$

which is an equation of an elliptic curve, which we formally define.

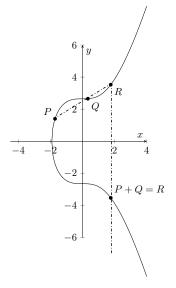

Figure 3: Demonstrating that two rational points P and Q on the elliptic curve E:  $y^2 = x^3 + 7$  generates a third rational point R. Note P + Q is the reflection of R about the x-axis.

RSA cryptography, which is based on groups arising from primes or the product of two distinct primes p and q,  $(\mathbb{Z}/pq\mathbb{Z})$ , was the gold standard in cryptography for years. However, it was also well-known that if we are able to factor a large number, then we can easily break RSA. Hence, it led to a search for other interesting groups with more complicated structure. Elliptic curves became the natural candidate because they have a group structure. Two points generate a third, but note that for the Pythagorean triples we only needed to find one point to generate them all. See [RG] for more details.

#### **1.3** Basic Concepts of Elliptic Curves

**Definition 1** (Elliptic Curve). We briefly review some basics of elliptic curves; see [ST] for more details. An elliptic curve in standard form has the form

$$y^2 = x^3 + ax + b, (1.13)$$

where  $a, b \in \mathbb{Q}$  and  $4a^3 + 27b^2 \neq 0$  because we want to avoid degenerate cases. For example, we do not want  $y^2 = x^2(x-1)$  to be an elliptic curve; when we send y to xy we get  $y^2 = x - 1$ , a parabola.

In this paper, we study two kinds of families of elliptic curves: one-parameter and twoparameter. For the families we compute in this paper, we can do a change of variable to make the elliptic curves look like what we write in the introduction, but for convenience we often have an  $x^2$  term.

**Definition 2** (One-Parameter Family of Elliptic Curves). A one-parameter family is of the form

$$\mathcal{E}: y^2 = x^3 + A(T)x + B(T), \tag{1.14}$$

with  $A(T), B(T) \in \mathbb{Q}[T]$ , which are polynomials of finite degree and rational coefficients.

**Definition 3** (Two-Parameter Family of Elliptic Curves). A two-parameter family is of the form

$$y^{2} = x^{3} + A(T, S)x + B(T, S), \qquad (1.15)$$

with  $A(T, S), B(T, S) \in \mathbb{Q}[T, S].$ 

**Theorem 1.3** (Mordell's Theorem). The group of rational points is finitely generated on a non-singular cubic elliptic curve.

Below we demonstrate the additional law and the point at infinity for an elliptic curve of rank 0 and an elliptic curve of rank 1. We can also see that as the rank of the elliptic curve increases, there are more points within a certain range of x.

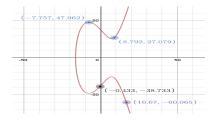

Figure 4: Points within the range  $|x| \leq 20$  on Rank 0 Elliptic Curve  $E: y^2 = x^3 + x^2 - 165x + 1427.$ 

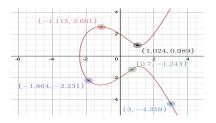

Figure 5: Points within the range  $|x| \leq 20$  on Rank 1 Elliptic Curve  $E: y^2 = x^3 - 4x + 4.$ 

Next, we define a characteristic of elliptic curves that is relevant to our paper. Often one can gain an understanding of a global object by studying a local one. In particular, for a prime p we can look at how often we have pairs (x, y) satisfying  $y^2 = x^3 + ax + b \mod p$ . As half of the non-zero elements of  $\mathbb{F}_p = \mathbb{Z}/p\mathbb{Z} = \{0, 1, 2, \dots, p-1\}$  are non-zero squares modulo p and the other half are not squares, it is reasonable to expect that for a randomly chosen x that half the time it will generate two solutions modulo p and half the time it will generate zero. Thus we expect the number of pairs to be of size p, and it is valuable to look at fluctuations about this expected number.

**Definition 4** (Fourier Coefficients). For *E* an elliptic curve  $y^2 = x^3 + ax + b$  and a prime *p*, we define the Fourier coefficients  $a_E(p)$  by

$$a_E(p) := p - |E(\mathbb{F}_p)|,$$
 (1.16)

where  $|E(\mathbb{F}_p)|$  is the number of solutions (x, y) to  $y^2 = x^3 + ax + b \mod p$  with  $x, y \in \mathbb{F}_p$ . These are used in constructing the associated L-function to the elliptic curve.

There is a very useful formula for  $a_E(p)$  (sometimes if the curve E is clear we write a(p) or  $a_p$ ). Recall the Legendre symbol  $\left(\frac{a}{p}\right)$ ; it is zero if a is zero modulo p, it is 1 if a is a non-zero square modulo p, and -1 otherwise. Thus  $1 + \left(\frac{x^3 + ax + b}{p}\right)$  is the number of solutions modulo p for a fixed x. If we sum this over all x modulo p we obtain  $|E(\mathbb{F}_p)|$ , and thus

$$a_E(p) = -\sum_{x \mod p} \left(\frac{x^3 + ax + b}{p}\right).$$
 (1.17)

**Definition 5** (Fourier Coefficients of A Specialized Curve). We specialize T to an integer t and obtain an elliptic curve  $\mathcal{E}_t$  with coefficients  $a_{\mathcal{E}_t}(p)$ :

$$a_{\mathcal{E}_t}(p) := p - |\mathcal{E}_t(\mathbb{F}_p)|, \qquad (1.18)$$

where  $|\mathcal{E}_t(\mathbb{F}_p)|$  is the number of points over  $\mathbb{F}_p$ , the finite field. As before, we have

$$a_{\mathcal{E}_t}(p) = -\sum_{x \mod p} \left( \frac{x^3 + A(t)x + B(t)}{p} \right).$$
 (1.19)

Much is known about the a(p)'s. For our work we only need to know their size, though recent breakthroughs have determined much more about their distribution.

**Theorem 1.4** (Hasse, 1931). The Riemann Hypothesis for finite fields holds if E is an elliptic curve and p a prime; we have

$$|a_E(p)| \leq 2\sqrt{p}. \tag{1.20}$$

Half of the time  $\left(\frac{x^3+A(t)x+B(t)}{p}\right)$  equals 1, and the other half time it is -1. The philosophy of square-root cancellation, similar to the Central Limit Theorem, predicts that if we sum p terms of size 1 with random signs, the results should be of size  $\sqrt{p}$ .

Last but not least, we define some other important characteristics of elliptic curves.

**Definition 6** (Moment of a One-Parameter Family). Let  $\mathcal{E}$  be a one parameter family of elliptic curves over  $\mathbb{Q}(T)$ , with  $\mathcal{E}_t$  the specialized curves. For each positive integer r, we define the  $r^{\text{th}}$  moment:

$$A_{\mathcal{E},r(p)} := \frac{1}{p} \sum_{t \bmod p} a_{\mathcal{E}_t}(p)^r.$$
(1.21)

There is a natural extension to two-parameter families, where we sum over s and t modulo p.

**Definition 7** (Big-Oh Notation). We say f = O(g(x)), read f the big-Oh of g, if there exists an  $x_0$  and a B > 0 such that for all  $x \ge x_0$  we have  $|f(x)| \le Bg(x)$ .

**Definition 8** (Rank). We can write the group of rational solutions of an elliptic curve E as an infinite lattice (r copies of  $\mathbb{Z}$ , where r is a non-negative integer) and a finite torsion part:

$$E(\mathbb{Q}) \cong \mathbb{Z}^r \times E(\mathbb{Q})_{\text{tors}}.$$
(1.22)

The geometric rank is the number of copies of  $\mathbb{Z}$ , or the number of independent points of infinite order. The analytic rank is the order of vanishing of the associated *L*-function at the central point. We move on to discuss one well-known problem of elliptic curve *L*-functions: the Birch and Swinnerton-Dyer conjecture.

## 1.4 Random Matrix Theory, Riemann Zeta Function, and the Birch and Swinnerton-Dyer Conjecture

The famous Millennium Prize Problem, the Birch and Swinnerton-Dyer Conjecture, is based on a *L*-function of an elliptic curve; it connects analysis to geometry, two great different fields of mathematics.

Given the inability to theoretically describe the energy levels of atoms more complicated than hydrogen, due to the complexities of the mathematics, physicists developed statistical approaches. Based on extensive numerical data, Wigner (Nobel Laureate in Physics, 1963) proposed that one could model nuclear physics through random matrices; that the behavior of eigenvalues in these matrix ensembles described the behavior of energy levels. As a result, two basic distributions that describe spacings between events, the Gaussian Orthogonal Ensemble (GOE) and the Gaussian Unitary Ensemble (GUE) were introduced.

Similarly, the zeroes of the Riemann Zeta function, which connects integers to primes and helps us understand the mysterious distribution of primes, seem to follow the RMT prediction too.

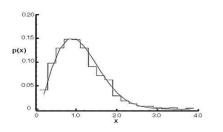

Figure 6: A Wigner distribution fitted to the spacing distribution of 932 s-wave resonances in the interaction Uranian + n at energies up to 20 keV.

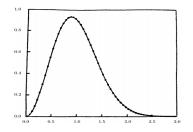

Figure 7: 70 million spacings between adjacent zeros of  $\zeta(s)$ , starting at the  $10^{20\text{th}}$  zero. The solid curve is the RMT prediction for the GUE ensemble, and the dots are the zeta zeros (from Odlyzko).

**Definition 9** (Riemann Zeta Function). We have for  $\operatorname{Re}(s) > 1$ 

$$\zeta(s) := \sum_{n=1}^{\infty} \frac{1}{n^s} = \prod_{p \text{ prime}} \left(1 - \frac{1}{p^s}\right)^{-1}.$$
(1.23)

The zeta function is defined as the sum over integers above, but its utility comes from the product expansion. The equivalence of these two expressions is due to the Fundamental Theorem of Arithmetic and the geometric series formula. Initially defined only for Re(s) > 1, the zeta function can be analytically continued to the entire complex plane with a simple pole of residue 1 at s = 1.

$$\xi(s) := \Gamma\left(\frac{s}{2}\right) \pi^{-\frac{s}{2}} \zeta(s) = \xi(1-s),$$
 (1.24)

where the line  $\operatorname{Re}(s) = 1/2$  is the critical line, and s = 1/2 the central point.

Its importance stems from the fact that by doing a contour integral of the logarithmic derivative of  $\zeta(s)$  and shifting contours, one obtains the Explicit Formula, which relates a sum over zeros to a sum over prime.

We now move on to discuss other *L*-functions.

**Definition 10** (*L*-function). The Hasse-Weil *L*-function of an elliptic curve  $E: y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6$  with coefficient  $a_E(p)$  and discriminant  $\Delta$ ,

$$\Delta := -b_2^2 b_8 - 8b_4^3 - 27b_6^2 + 9b_2 b_4 b_6, \qquad (1.25)$$

where  $b_2 = a_1^2 + 4a_4$ ,  $b_4 = 2a_4 + a_1a_3$  and  $b_6 = a_3^2 + 4a_6$ , is defined as

$$L(s,E) := \prod_{p|\Delta} \frac{1}{1 - a_p p^{-s}} \prod_{p \nmid \Delta} \frac{1}{1 - a_p p^{-s} + p^{1-2s}}.$$
 (1.26)

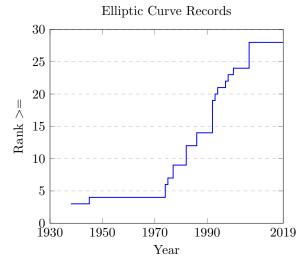

See [Kn].

Similar to the zeta function, these L-functions take local data and create a global object, from which much can be deduced. The most important of these inferences is the famous Birch and Swinnerton-Dyer conjecture.

**Conjecture 1.5** (Birch and Swinnerton-Dyer Conjecture). The order of vanishing of L(E, s) at the central point s = 1 is equal to the rank of the group of rational points  $E(\mathbb{Q})$ .

In other words, Birch and Swinnerton-Dyer conjectured that the geometric rank of an elliptic curve equals its analytic rank.

Unfortunately, it is not known what values of rank r are possible for an elliptic curve. In 1938, Billing found an elliptic curve with rank 3. The largest known rank increased over the next few decades. The largest is due to Elkies in 2006, and is rank at least 28. Interestingly, there are not examples of elliptic curves for each rank smaller than 28 (see [Du] for a more comprehensive historical data on elliptic curve records). While originally it was thought that the ranks are unbounded, now some conjecture that this is not the case.

#### 1.5 The Bias Conjecture

Similar to using the Riemann Zeta function to understand the distribution of primes, we use the Explicit Formula (see [KS]), which relates sums over primes of the Fourier coefficients  $a_E(p)$  and  $a_E^2(p)$  to sums of test functions over zeros, to deduce information about the zeros. Let us look at a one-parameter family  $\mathcal{E}: y^2 = x^3 + A(t)x + B(t)$ , with  $t \in [N, 2N]$ , and where  $\phi$ is an even Schwartz-class function that decays rapidly (this means  $\phi$ , and all of its derivatives, decay faster than  $1/(1 + |x|)^A$  for any A > 0), log R is the average log conductor, and  $1 + i\gamma$ are the non-trivial zeros of the *L*-function:

$$\frac{1}{N}\sum_{t=N}^{2N}\sum_{\gamma_t}\phi\left(\gamma_t\frac{\log R}{2\pi}\right) = \widehat{\phi}(0) + \phi(0) - \frac{2}{N}\sum_{t=N}^{2N}\sum_p\frac{\log p}{\log R}\frac{1}{p}\widehat{\phi}\left(\frac{\log p}{\log R}\right)a_t(p) - \frac{2}{N}\sum_{t=N}^{2N}\sum_p\frac{\log p}{\log R}\frac{1}{p^2}\widehat{\phi}\left(\frac{2\log p}{\log R}\right)a_t(p)^2 + O\left(\frac{\log\log R}{\log R}\right);$$
(1.27)

the result above comes from integrating the logarithmic derivative of the *L*-function against the Schwartz test function  $\phi$  and then shifting contours. If the generated Riemann Hypothesis is true then  $\gamma \in \mathbb{R}$ .

Note that if the test function is non-negative, then dropping the contributions of  $\phi$  at all the zeros that are not at the central point removes a non-negative amount from the left hand side. The right hand side then becomes an upper bound for the average rank of the elliptic curves in the family:

$$\frac{1}{N}\sum_{t=N}^{2N}\sum_{\gamma_t=0}\phi(0) \leq \widehat{\phi}(0) + \phi(0) - \frac{2}{N}\sum_{t=N}^{2N}\sum_p \frac{\log p}{\log R} \frac{1}{p}\widehat{\phi}\left(\frac{\log p}{\log R}\right)a_t(p) - \frac{2}{N}\sum_{t=N}^{2N}\sum_p \frac{\log p}{\log R} \frac{1}{p^2}\widehat{\phi}\left(\frac{2\log p}{\log R}\right)a_t(p)^2 + O\left(\frac{\log\log R}{\log R}\right),$$
(1.28)

which means that

$$\phi(0) * \operatorname{AverageRank}(N) \leq \widehat{\phi}(0) + \phi(0) - \frac{2}{N} \sum_{t=N}^{2N} \sum_{p} \frac{\log p}{\log R} \frac{1}{p} \widehat{\phi}\left(\frac{\log p}{\log R}\right) a_t(p) - \frac{2}{N} \sum_{t=N}^{2N} \sum_{p} \frac{\log p}{\log R} \frac{1}{p^2} \widehat{\phi}\left(\frac{2\log p}{\log R}\right) a_t(p)^2 + O\left(\frac{\log\log R}{\log R}\right).$$

$$(1.29)$$

Thus when  $\phi$  is non-negative, we obtain a bound for the average rank in the family by restricting the sum to be only over zeros at the central point. The error  $O\left(\frac{\log \log R}{\log R}\right)$  comes from trivial estimation and ignores probable cancellation, and we expect  $O\left(\frac{1}{\log R}\right)$  or smaller to be the correct magnitude. For most one-parameter families of elliptic curves we have  $\log R \sim \log N^a$  for some integer a, where  $t \in [N, 2N]$ .

The main term of the first and second moments of the  $a_t(p)$  give  $\phi(0)$  \*AverageRank(N) and  $-\frac{1}{2}\phi(0)$ ; this is a standard application of the prime number theorem to evaluate the resulting sums; for details see the appendices on prime sums in [Mi1]. This is reminiscent of the Central Limit Theorem, where so long as some weak conditions are satisfied for independent, identically distributed random variables, their normalized sum converges to the standard normal. In that setting, if the moments are finite we can always adjust our distribution to have mean zero

and variance one, and it is only these moments that enter the limiting analysis. The higher moments *do* have an impact, but it is only through the lower order terms, which control the *rate* of convergence.

We have a similar situation here. First, the higher moments of our Fourier coefficients contribute in the big-Oh terms  $O\left(\frac{1}{\log R}\right)$ . Second, the lower order terms in the first and second moments can contribute, but not to the main term in the expansions above. Explicitly, assume the second moment of  $a_t(p)^2$  is  $p^2 - m_{\mathcal{E}}p + O(1)$ ,  $m_{\mathcal{E}} > 0$ . We have already handled the contribution from  $p^2$ , and  $-m_{\mathcal{E}}p$  contributes

$$S_{2} \sim \frac{-2}{N} \sum_{p} \frac{\log p}{\log R} \widehat{\phi} \left( 2 \frac{\log p}{\log R} \right) \frac{1}{p^{2}} \frac{N}{p} (-m_{\mathcal{E}}p)$$
$$= \frac{2m_{\mathcal{E}}}{\log R} \sum_{p} \widehat{\phi} \left( 2 \frac{\log p}{\log R} \right) \frac{\log p}{p^{2}}.$$
(1.30)

We have a prime sum which converges between  $\phi$  that decays, and this sum is bounded by  $\sum_p \log p/p^2$ . Thus,  $S_2$  converges and there is a contribution of size  $1/\log(R)$ . This is the motivation behind why the Bias Conjecture, which S. J. Miller conjectured in his thesis [Mi1], matters, as a bias has an impact in our estimates on the rank and the behavior of zeros near the central point.

**Conjecture 1.6** (Bias Conjecture for the Second Moment of Fourier Coefficients of Elliptic Curve *L*-Functions). Consider a family of elliptic curves. Then the largest lower term in the second moment expansion of a family which does not average to 0 is on average negative.

If the Bias Conjecture holds, then when we estimate the rank of a family, there is always an extra term that slightly increases our upper bound for the average rank. This amount decreases as  $\log R$  grows, and thus in the limit plays no role; however, it does lead to a small but noticeable contribution for small and modest sized conductors.

#### 1.6 Our Results

Now we report on the results of our research. Much is known about the first moment of the Fourier coefficients of elliptic curves. Work of Nagao, Rosen and Silverman shows that the first moment in families is related to the rank of the family over  $\mathbb{Q}(T)$ ; specifically, a small negative bias results in rank. This was used by Arms, Lozano-Robledo and Miller [ALM] to construct one-parameter families of elliptic curves with moderate rank.

It is thus natural to ask if there is a bias in the second moments, and if so what are the consequences. One important one, due to Miller [Mi3], is that a negative bias here is related to

some of the observed excess rank and repulsion of zeros of elliptic curve L-functions near the central point for finite conductors.

We start with a result from Michel on the main term of the second moments, and the size of the fluctuations, in one-parameter families.

**Theorem 1.7.** For a one-parameter family  $\mathcal{E} : y^2 = x^3 + A(T)x + B(T)$  with non-constant j(T)-invariant  $j(T) = 1728 \frac{4A(T)^3}{4A(T)^3 + 27B(T)^2}$ , Michel has proven that in the second moment of the Fourier coefficients equals

$$pA_{2,\mathcal{E}}(p) = p^2 + O(p^{3/2}),$$
 (1.31)

with the lower order terms of size  $p^{3/2}$ , p,  $p^{1/2}$  and 1 having important cohomological interpretations.

**Theorem 1.8** (Birch Theorem). For the family  $\mathcal{E} : y^2 = x^3 + ax + b$  of all elliptic curves, the second moment of the Fourier coefficient equals:

$$pA_{2,\mathcal{F}}(p) = \sum_{a,b \mod p} a_{\mathcal{F}_{a,b}}(p) = p^3 - p^2.$$
 (1.32)

See [Bi, Mi1, Mi3, Mic].

Unfortunately it is very hard to compute in closed form Legendre sums arising from an elliptic curve, though we will see later that we can compute linear and quadratic Legendre sums easily. Thus, in all our investigations below, we are forced to restrict our analysis to families where the resulting sums are tractable. There is therefore a danger that we are not looking at generic families.

Below is a summary of the new families we have successfully studied. In addition to several new one-parameter families, in this work two-parameter families are studied for the first time. For the two rank 2 one-parameter families we are unable to compute in closed form, we demonstrate convincing results that for small primes the bias conjecture holds in them. We set  $\delta_1(p)$ to be 1 if  $p \equiv 1 \mod 4$  and 0 otherwise, and  $\delta_3(p)$  to be 1 if  $p \equiv 3 \mod 4$  and 0 otherwise.

One-Parameter Family	Rank	$pA_{1,\mathcal{F}}(p)$	$pA_{2,\mathcal{F}}(p)$
$y^2 = x^3 - x^2 - x + t$	0	0	$p^2 - 2p - \left(\frac{-3}{p}\right)p$
$y^2 = x^3 - tx^2 + (x - 1)t^2$	0	0	$p^{2} - 2p - \left[\sum_{x(p)} \left(\frac{x^{3} - x^{2} + x}{p}\right)\right]^{2} - \left(\frac{-3}{p}\right)p$
$y^2 = x^3 + tx^2 + t^2$	1	-р	$p^2 - 2p - \left(\frac{-3}{p}\right)p - 1$
$y^2 = x^3 + tx^2 + x + 1$	1	-р	$p^2 - p - 1 + p \sum_{x(p)} \left(\frac{4x^3 + x^2 + 2x + 1}{p}\right)$
$y^2 = x^3 + tx^2 + tx + t^2$	1	-р	$p^2 - p - 1 - \delta_1(p)(2p)$
$y^2 = x^3 - x^2 + (x^2 - x)t + 1$	2	-2p	$p^2 - 1$ (conjectured)
$y^2 = x^3 - x + t^4$	2 (conjectured)	-2p (conjectured)	$p^2 - p$ (conjectured)

Table 1: The one-parameter families we proved theoretically all show that the largest lower order term that does not average to zero has a negative average. Unfortunately, we are not able to prove the second moment of  $y^2 = x^3 - x^2 + (x^2 - x)t + 1$  as well as the first and second moment of  $y^2 = x^3 - x + t^4$  theoretically. We only generated data for the first 100 primes to get a sense of the behavior as no finite computation will be a proof. Also, keep in mind that we did not observe the same form for every prime; we conjectured the average of its first or second moment. One family worth noting is  $y^2 = x^3 - x^2 + (x^2 - x)t + 1$ ; it is a potential counterexample to a stronger form of Miller's Bias Conjecture based on the families studied to date, which is that in the second moment expansion the first term that does not average to zero is the *p* term and that has a negative average.

Two-Parameter Family	$p^2 A_{1,\mathcal{F}}(p)$	$p^2 A_{2,\mathcal{F}}(p)$
$y^2 = x^3 + tx + sx^2$	0	$p^3 - 2p^2 + p$
$y^2 = x^3 + t^2x + st^4$	0	$p^3 - 2p^2 + p - 2(p^2 - p)\left(\frac{-3}{p}\right)$
$y^2 = x^3 + sx^2 - t^2x$	0	$p^3 - p^2 - \delta_3(p)(2p^2 - 2p)$
$y^2 = x^3 + ts^2x^2 + (t^3 - t^2)x$	$-p^{2}$	$p^3 - 3p^2 + 3p - 1 - \delta_3(p)(2p - 2)$
$y^{2} = x^{3} + t^{2}x^{2} + (t^{3} - t^{2})sx$	$-p^2$	$p^3 - 3p^2 + 3p - \delta_3(p)(2p^2 - 4p)$
$y^2 = x^3 + t^2 x^2 - (s^2 - s)t^2 x$	$-2p^{2}$	$p^{3} - 3p^{2} + 2p + \delta_{1}(p) \left( p - \sum_{s(p)} \sum_{x,y(p)} \left( \frac{x^{3} - (s^{2} - s)x}{p} \right) \left( \frac{y^{3} - (s^{2} - s)y}{p} \right) \right)$
$y^2 = x^3 - t^2x + t^3s^2 + t^4$	$-2p^{2}$	$p^3 - 2p^2 + p - \left[\left(\frac{-3}{p}\right) + \left(\frac{3}{p}\right)\right]p^2$

Table 2: The two-parameter families we proved theoretically all show a negative bias in the largest lower order term in the second-moment expansion.

### 2 Tools for Calculating Biases

In this section we explain why we can use rank as the first moment, and then introduce the linear and quadratic Legendre sums, the Jacobi symbol as well as the Gauss Sum Expansion, which can be used to compute biases in elliptic curves. See more details from [RoSi, BEW, BAU, Mi1].

**Theorem 2.1** (Rosen-Silverman). For an elliptic surface (a one-parameter family), if Tate's conjecture holds, the first moment is related to the rank of the family over  $\mathbb{Q}(T)$ :

$$\lim_{x \to \infty} \frac{1}{x} \sum_{p \le x} \frac{A_1, \mathcal{E}(p) \log p}{p} = \operatorname{rank} \mathcal{E}(\mathbb{Q}(\mathbf{T})).$$
(2.1)

**Conjecture 2.2** (Tate's Conjecture for Elliptic Surfaces [ST]). Let  $\mathcal{E}/\mathbb{Q}$  be an elliptic surface and  $L_2(\mathcal{E},s)$  be the L-series attached to  $H^2_{et}(\mathcal{E}/\mathbb{Q},\mathbb{Q}_l)$ . Then  $L_2(\mathcal{E},s)$  has a meromorphic continuation to C and satisfies

$$-\operatorname{ord}_{s=2}L_2(\mathcal{E}, s) = \operatorname{rank} NS(\mathcal{E}/\mathbb{Q}), \qquad (2.2)$$

where  $NS(\mathcal{E}/\mathbb{Q})$  is the Q-rational part of the Neron-Severi group of  $\mathcal{E}$ . Further,  $L_2(\mathcal{E}, s)$  does not vanish on the line Re(s) = 2.

Tate's conjecture is known to hold for rational surfaces: An elliptic curve  $y^2 = x^3 + A(T)x + B(T)$ is rational iff one of the following is true:

- 1.  $0 < \max(3 \deg A, 2 \deg B) < 12$ ,
- 2.  $3 \deg A = 2 \deg B = 12$  and  $\operatorname{ord}_{T=0} T^{12} \Delta(T^{-1}) = 0$ .

All of the one-parameter families we compute are rational surfaces. See Appendix B for the complete proofs. However, for two-parameter families, we cannot use the Rosen-Silverman theorem, and for us the ranks are conjectural. Checking their ranks is beyond the scope of this paper, but it can be done; see [WAZ] for more details. As our interest is in the biases of the second moments, we do not need to know these ranks for our purposes.

The key to our analysis in the families below are closed form expressions for linear and quadratic Legendre sums.

**Lemma 2.3.** Let a, b, c be positive integers and  $a \not\equiv 0 \mod p$ . Then

$$\sum_{x \bmod p} \left( \frac{ax+b}{p} \right) = 0, \text{ if } p \nmid a, \tag{2.3}$$

and

$$\sum_{x \bmod p} \left(\frac{ax^2 + bx + c}{p}\right) = \begin{cases} -\left(\frac{a}{p}\right), & \text{if } p \nmid b^2 - 4ac\\ (p-1)\left(\frac{a}{p}\right), & \text{if } p \mid b^2 - 4ac. \end{cases}$$
(2.4)

By Dirichlet's theorem for primes in arithmetic progression, to first order as N tends to infinity there are the same number of primes congruent to 1 mod 4 as there are congruent to 3 mod 4. Thus, up to lower order terms tending to zero as N goes to infinity, the average is controlled by the following lemma. We have

$$\left(\frac{-1}{p}\right) = \begin{cases} 1, \text{ if } n \equiv 1 \mod 4. \\ -1, \text{ if } n \equiv 3 \mod 4. \end{cases}$$
(2.5)

See [VAR] for more details.

For some of our families, we need an alternative expansion for the Fourier coefficients.

**Lemma 2.4** (Quadratic Formula mod p). For a quadratic  $ax^2 + bx + c \equiv 0 \mod p$ ,  $a \neq 0$ , there are two distinct roots if  $b^2 - 4ac$  equals to a non-zero square, one root if  $b^2 - 4ac \equiv 0$ , and zero roots if  $b^2 - 4ac$  is not a square.

See [Mi1] for more details.

**Lemma 2.5** (Gauss Sum Expansion). We have the following expansion of  $\left(\frac{x}{n}\right)$ :

$$\left(\frac{x}{p}\right) = G_p^{-1} \sum_{c=1}^p \left(\frac{c}{p}\right) \boldsymbol{e}\left(\frac{cx}{p}\right)$$
(2.6)

where  $G_p = \sum_{a(p)} \left(\frac{a}{p}\right) \boldsymbol{e}\left(\frac{a}{p}\right)$ , which equals to  $\sqrt{p}$  for  $p \equiv 1(4)$  and  $i\sqrt{p}$  for  $p \equiv 3(4)$ . For the curve  $y^2 = f_E(x), a_E(p) = -\sum_{x(p)} \left(\frac{f_E(x)}{p}\right)$ . We expand the x-sum by using Gauss sums, namely

$$a_E(p) = G_p^{-1} \sum_{x(p)} \sum_{c=1}^p \left(\frac{c}{p}\right) e\left(\frac{cf_E(x)}{p}\right)$$
(2.7)

See examples of Gauss Sum Expansion in [BEW].

Sadly, there are no nice closed form expressions for cubic and higher sums, which is why elliptic curves are so hard to analyze as we need cubic sums for the coefficients. Hence, we choose special families where, after changing the order of summation, we get beautiful reinforcement and can execute in these special cases. Thus, there is a search for families that lead to tractable sums after changing.

## 3 Biases in First and Second Moments in One-Parameter Families

We proved in Appendix B that every one-parameter family we computed are rational surfaces, so their first moment is equivalent to their rank.

#### 3.1 Construction of Rank 0 Families

**3.1.1** 
$$y^2 = x^3 - x^2 - x + t$$

**Lemma 3.1.** The first moment of the one-parameter family  $y^2 = x^3 - x^2 - x + t$  is 0. Since it is a rational surface, we can use the Rosen-Silverman theorem and the family's rank is 0. *Proof.* For p > 3,

$$-pA_{1,\mathcal{F}}(p) = \sum_{t=0}^{p-1} \sum_{x=0}^{p-1} \left(\frac{x^3 - x^2 - x + t}{p}\right)$$

$$= \sum_{x=0}^{p-1} \sum_{t=0}^{p-1} \left( \frac{t + (x^3 - x^2 - x)}{p} \right) = 0.$$
(3.1)

By the linear Legendre sum formula (Lemma 2.3), the *t*-sum is 0 if the equation is in the form of at + b. Therefore,  $\sum_{t(p)} \sum_{x(p)} \left(\frac{x^3 - x^2 - x + t}{p}\right)$  equals to 0.

**Lemma 3.2.** The second moment of the one-parameter family  $y^2 = x^3 - x^2 - x + t$  times p is  $p^2 - 2p - \left(\frac{-3}{p}\right)p$ , which supports our Bias Conjecture.

Proof.

$$pA_{2,\mathcal{F}}(p) = \sum_{t(p)} a_t^{2}(p)$$
  
= 
$$\sum_{t(p)} \sum_{x,y(p)} \left(\frac{x^3 - x^2 - x + t}{p}\right) \left(\frac{y^3 - y^2 - y + t}{p}\right)$$
(3.2)

Now, we compute the discriminant of the equation in t, denoted as  $\delta$ , which we then evaluate the quadratic Legendre sums (Lemma 2.3) to compute the second moment:

$$a = 1$$
  

$$b = (x^{3} - x^{2} - x) + (y^{3} - y^{2} - y)$$
  

$$c = (x^{3} - x^{2} - x)(y^{3} - y^{2} - y)$$
  

$$\delta = b^{2} - 4ac = [(x^{3} - x^{2} - x) - (y^{3} - y^{2} - y)]^{2}.$$
(3.3)

We see that  $\delta(x, y)$  can be rewritten as

$$(x-y)(x^{2}+xy-x+y^{2}-y-1).$$
(3.4)

(3.5)

We can see that  $\delta(x, y) \equiv 0$  if x = y and this happens p times. By the Quadratic Formula Mod p (Lemma 2.4),  $\delta_2(x, y) = x^2 + xy - x + y^2 - y - 1 = y^2 + (x - 1)y + (x^2 - x - 1) \equiv 0$  when  $y = \frac{-x + 1 \pm \sqrt{-3x^2 + 2x + 5}}{2}$ ,

which reduces to find when  $-3x^2 + 2x + 5$  is a square mod p. We get 2 distinct values of y if it is equivalent to a non-zero square, 1 value if it equals to 0, and no value if it does not equal to a square. When solving  $\delta_2(x, y) \equiv 0 \mod p$ , we need to make sure  $y \notin (0)$ . The number of solutions to  $\delta_2(x, y) = x^2 + xy - x + y^2 - y - 1 \equiv 0(p)$  equals to:

$$\sum_{x=1}^{p-1} \left( 1 + \left( \frac{-3x^2 + 2x + 5}{p} \right) \right) = p - 1 + \sum_{x=1}^{p-1} \left( \frac{-3x^2 + 2x + 5}{p} \right)$$
$$= p + \sum_{x(p)} \left( \frac{-3x^2 + 2x + 5}{p} \right).$$
(3.6)

Then, we use Quadratic Formula Mod p (Lemma 2.4) again. The discriminant now equals to 4 - 4(-3)5 = 64. For  $p \ge 3$ , p does not divide discriminant, so the sum is  $p - \left(\frac{-3}{p}\right)$ .

Then we check if there are any double-counting cases. If both factors are congruent to zero, we have  $3x^2 - 2x - 1 \equiv 0$  when  $x = 1, -3^{-1}$ . Thus, the total number of pairs is

$$2p - 2 - \left(\frac{-3}{p}\right). \tag{3.7}$$

Therefore,

$$pA_{2,\mathcal{F}}(p) = p\left[2p - 2 - \left(\frac{-3}{p}\right)\right] - p^2$$
$$= p^2 - 2p - \left(\frac{-3}{p}\right)p.$$
(3.8)

**3.1.2** 
$$y^2 = x^3 - tx^2 + (x - 1)t^2$$

**Lemma 3.3.** The first moment of the one-parameter family  $y^2 = x^3 - tx^2 + (x - 1)t^2$  is 0. Since it is a rational surface, we can use the Rosen-Silverman theorem and the family's rank is 0.

Proof.

$$\begin{aligned} -pA_{1,\mathcal{F}}(p) &= -\sum_{t(p)} a_{t(p)} = \sum_{t(p)} \sum_{x(p)} \left( \frac{x^3 - tx^2 + (x-1)t^2}{p} \right) \\ &= \sum_{t(p)} \sum_{x(p)} \left( \frac{x^3 - tx^2 + xt^2 - t^2}{p} \right) \\ &= \sum_{t=1}^{p-1} \sum_{x(p)} \left( \frac{t^3x^3 - t^3x^2 + t^3x - t^2}{p} \right) \\ &= \sum_{x(p)} \sum_{t=1}^{p-1} \left( \frac{t^2}{p} \right) \left( \frac{tx^3 - tx^2 + tx - 1}{p} \right) \end{aligned}$$

$$= \sum_{x(p)} \sum_{t=0}^{p-1} \left( \frac{t(x^3 - x^2 + x) - 1}{p} \right) - \sum_{x(p)} \left( \frac{-1}{p} \right)$$
  

$$= \sum_{t(p)} \sum_{x=0} \left( \frac{-1}{p} \right) + \sum_{t(p)} \sum_{x(p); x \neq 0} \left( \frac{t(x^3 - x^2 + x) - 1}{p} \right) - \sum_{x(p)} \left( \frac{-1}{p} \right)$$
  

$$= -p + 0 + p$$
  

$$= 0$$
  
(3.9)

**Lemma 3.4.** The second moment of the one-parameter family  $y^2 = x^3 - tx^2 + (x-1)t^2$  times p is  $p^2 - 2p - \left(\frac{-3}{p}\right)p - 1$ , which supports our Bias Conjecture.

$$pA_{2,\mathcal{F}}(p) = \sum_{t(p)} a_t^{2}(p)$$

$$= \sum_{t(p)} \sum_{x(p)} \sum_{y(p)} \left( \frac{x^3 - tx^2 + xt^2 - t^2}{p} \right) \left( \frac{y^3 - ty^2 + yt^2 - t^2}{p} \right)$$

$$= \sum_{t=1}^{p-1} \sum_{x,y(p)} \left( \frac{t^3x^3 - t^3x^2 + t^3x - t^2}{p} \right) \left( \frac{t^3y^3 - t^3y^2 + t^3y - t^2}{p} \right)$$

$$= \sum_{t=1}^{p-1} \sum_{x,y(p)} \left( \frac{t^4}{p} \right) \left( \frac{t(x^3 - x^2 + x) - 1}{p} \right) \left( \frac{t(y^3 - y^2 + y) - 1}{p} \right)$$

$$= \sum_{t=0}^{p-1} \sum_{x,y(p)} \left( \frac{t(x^3 - x^2 + x) - 1}{p} \right) \left( \frac{t(y^3 - y^2 + y) - 1}{p} \right) - \sum_{x,y(p)} \left( \frac{-1}{p} \right) \left( \frac{-1}{p} \right)$$

$$= \sum_{t(p)} \sum_{x,y(p)} \left( \frac{t(x^3 - x^2 + x) - 1}{p} \right) \left( \frac{t(y^3 - y^2 + y) - 1}{p} \right) - p^2$$
(3.10)

We compute the discriminant of the equation in terms of t:

$$a = (x^{3} - x^{2} + x)(y^{3} - y^{2} + y)$$
  

$$b = -[(x^{3} - x^{2} + x) + (y^{3} - y^{2} + y)]$$
  

$$c = 1$$
  

$$\delta = b^{2} - 4ac = [(x^{3} - x^{2} + x) - (y^{3} - y^{2} + y)]^{2}.$$
(3.11)

The only two ways that at least  $(x^3 - x^2 + x)$  or  $(y^3 - y^2 + y)$  vanishes are when x = 0 and y = 0. Hence, the total contribution is 2p.

We can rewrite  $\delta(x, y)$  as  $(x - y)(x^2 + xy - x + y^2 - y + 1)$ . Like what we do for the previous several families, we see that  $x = y \neq 0$  so the contribution from it is p - 1.

Let  $\delta_2(x,y)$  be  $(x^2 + xy - x + y^2 - y + 1)$ . Using Lemma 2.4, we have:

$$y = \frac{-(x-1) \pm \sqrt{(x-1)^2 - 4(x^2 - x + 1)}}{2}$$
$$= \frac{-(x-1) \pm \sqrt{-3x^2 + 2x - 3}}{2}.$$
(3.12)

Hence, the number of solutions to  $\delta_2(x, y) \equiv 0$  is:

$$\sum_{x=1}^{p-2} \left[ 1 + \left( \frac{-3x^2 + 2x - 3}{p} \right) \right] = p - 2 + \left( \frac{-3x^2 + 2x - 3}{p} \right).$$
(3.13)

We use Lemma 2.4 again. The discriminant now is  $2^2 - 4(-3)(-3)$ . Hence, for p > 5, p does not divide the discriminant, and the sum is  $-\left(\frac{-3}{p}\right)$ .

Since we don't have double-counted solutions, the total number of pairs is

$$2p - 4 - \left(\frac{-3}{p}\right).\tag{3.14}$$

When  $x = y \neq 0$ , clearly  $\left(\frac{(x^3 - x^2 + x)(y^3 - y^2 + y)}{p}\right) = 1$  and these terms each contribute 1. Consider  $x \neq y \neq 0$  and  $x^2 + xy - x + y^2 - y + 1 \equiv 0$ . Then  $x^2 - x + 1 \equiv y(-y + 1 - x)$  and

 $y^2 - y + 1 \equiv x(-x + 1 - y)$  and

$$\left(\frac{(x^3 - x^2 + x)(y^3 - y^2 + y)}{p}\right) = \left(\frac{xy(-x + 1 - y)^2}{p}\right).$$
(3.15)

We can see that  $x \neq y$ , so all pairs have their Legendre factor +1. Therefore,

$$pA_{2,\mathcal{F}}(p) = p\left(2p - 4 - \left(\frac{-3}{p}\right)\right) - \sum_{x,y(p)} \left(\frac{(x^3 - x^2 + x)(y^3 - y^2 + y)}{p}\right) + 2p - p^2$$
$$= p^2 - 2p - \left[\sum_{x(p)} \left(\frac{x^3 - x^2 + x}{p}\right)\right]^2 - \left(\frac{-3}{p}\right)p.$$
(3.16)

Now we move on to construct some rank 1 families.

#### **3.2** Construction of Rank 1 Families

**3.2.1**  $y^2 = x^3 + tx^2 + t^2$ 

**Lemma 3.5.** The first moment of the one-parameter family  $y^2 = x^3 + tx^2 + t^2$  is -1, and the family's rank is 1.

Proof.

$$\begin{aligned} -pA_{1,\mathcal{F}}(p) &= -\sum_{t(p)} a_{t(p)} = \sum_{t(p)} \sum_{x(p)} \left( \frac{x^3 + tx^2 + t^2}{p} \right) \\ &= \sum_{t=1}^{p-1} \sum_{x(p)} \left( \frac{t^3 x^3 + t^3 x^2 + t^2}{p} \right) \\ &= \sum_{t=1}^{p-1} \sum_{x(p)} \left( \frac{t^2}{p} \right) \left( \frac{t(x^2 + x^3) + 1}{p} \right) \\ &= \sum_{t(p)} \sum_{x(p)} \left( \frac{t(x^2 + x^3) + 1}{p} \right) - \sum_{x(p)} \left( \frac{1}{p} \right) \\ &= \sum_{t(p)} \sum_{x(p)} \left( \frac{tx^3 + tx^2 + 1}{p} \right) - \sum_{x(p)} \left( \frac{1}{p} \right) \\ &= \sum_{t(p)} \sum_{x(p)} \sum_{x=0,-1} \left( \frac{1}{p} \right) + \sum_{x\neq 0,-1} \sum_{t(p)} \left( \frac{t+1}{p} \right) - p \\ &= 2p + 0 - p \\ &= p \end{aligned}$$

(3.17)

We apply the linear Legendre sums. Since  $\left(\frac{t^2}{p}\right)$  yields 1, we can ignore it and separate  $\left(\frac{t(x^3+x^2)+1}{p}\right)$  into two cases: when t = 0 and when  $t \neq 0$ . When t = 0, the sum is  $\sum_{x(p)} \left(\frac{1}{p}\right) = p$  and we subtract it from the total sum. When  $t \neq 0$ , we have 2p when x = 0, -1 so that  $x^3 + x^2 \equiv 0$  mod p. Hence, the total contribution is 2p - p = p.

**Lemma 3.6.** The second moment of the one-parameter family  $y^2 = x^3 + tx^2 + t^2$  times p is  $p^2 - 2p - \left(\frac{-3}{p}\right)p - 1$ , which supports our Bias Conjecture.

Proof.

$$pA_{2,\mathcal{F}}(p) = \sum_{t(p)} a_t^{2}(p)$$

$$= \sum_{t(p)} \sum_{x,y(p)} \left(\frac{x^3 + tx^2 + t^2}{p}\right) \left(\frac{y^3 + ty^2 + t^2}{p}\right)$$

$$= \sum_{t=1}^{p-1} \sum_{x,y(p)} \left(\frac{x^3 + tx^2 + t^2}{p}\right) \left(\frac{y^3 + ty^2 + t^2}{p}\right)$$

$$= \sum_{t=1}^{p-1} \sum_{x,y(p)} \left( \frac{t^3 x^3 + t^3 x^2 + t^2}{p} \right) \left( \frac{t^3 y^3 + t^3 y^2 + t^2}{p} \right)$$

$$= \sum_{t=1}^{p-1} \sum_{x,y(p)} \left( \frac{t^4}{p} \right) \left( \frac{t(x^3 + x^2) + 1}{p} \right) \left( \frac{t(y^3 + y^2) + 1}{p} \right)$$

$$= \sum_{t=0}^{p-1} \sum_{x,y(p)} \left( \frac{t^4}{p} \right) \left( \frac{t(x^3 + x^2) + 1}{p} \right) \left( \frac{t(y^3 + y^2) + 1}{p} \right) - \sum_{x,y(p)} \left( \frac{1}{p} \right)$$

$$= \sum_{x,y(p)} \sum_{t=0}^{p-1} \left( \frac{t(x^3 + x^2) + 1}{p} \right) \left( \frac{t(y^3 + y^2) + 1}{p} \right) - p^2$$
(3.18)

Its discriminant is:

$$a = (x^{3} + x^{2})(y^{3} + y^{2})$$
  

$$b = x^{3} + x^{2} + y^{3} + y^{2}$$
  

$$c = 1$$
  

$$\delta = b^{2} - 4ac = ((x^{3} + x^{2}) - (y^{3} + y^{2}))^{2}.$$
  
(3.19)

First, we calculate the cases when at least  $(x^3 + x^2)$  or  $(y^3 + y^2)$  vanishes. When x = 0, -1,  $(x^3 + x^2)$  equals to zero. Then, we have  $\sum_t \left(\frac{t(y^3 + y^2) + 1}{p}\right)$ , which is 2p from our  $A_{1,\mathcal{F}(p)}$ . Similarly, we have 2p for  $\sum_t \left(\frac{t(x^3 + x^2) + 1}{p}\right)$ . We overcount by 4p when both  $x^3 + x^2$  and  $y^3 + y^2$  are equivalent to 0. Therefore, the total sum of that at least  $(x^3 + x^2)$  or  $(y^3 + y^2)$  vanishes equals to 2p + 2p - 4p = 0.

Then, assume  $x, y \notin \{0, -1\}$ . When  $\delta(x, y) \equiv 0 \mod p$ , we have

$$\delta(x,y) = (x-y)(x^2 + xy + x + y^2 + y).$$
(3.20)

Therefore,

$$pA_{2,\mathcal{F}}(p) = \sum_{x,y\neq 0,-1;\delta(x,y)\equiv 0} p\left(\frac{(x^3+x^2)(y^3+y^2)}{p}\right) - \sum_{x,y\neq 0,-1} \left(\frac{(x^3+x^2)(y^3+y^2)}{p}\right) - p^2. \quad (3.21)$$

We can see that  $\delta(x, y) \equiv 0$  if x = y and this happens p times. If x = y, then the second factor equals to  $3x^2 + 2x$ , which is congruent to zero at most twice.

By Lemma 2.4,  $\delta_2(x, y) = x^2 + xy + x + y^2 + y \equiv 0$  when

$$y = \frac{-x - 1 \pm \sqrt{-3x^2 - 2x + 1}}{2},$$

(3.22)

which reduces to find when  $-3x^2 - 2x + 1$  is a square mod p. We get 2 distinct values of y if it is equivalent to a non-zero square, 1 value if it equals to 0, and no value if it does not equal to a square. When we solve  $\delta_2(x, y) \equiv 0 \mod p$ , we need to make sure  $y \notin (0, -1)$ . If y = 0, then x = -1; if y = -1, then x = 0. Therefore, we don't get an excluded y. Thus, the number of solutions to  $\delta_2(x, y) = x^2 + xy + x + y^2 + y \equiv 0$  equals to:

$$\sum_{x=1}^{p-2} \left[ 1 + \left( \frac{-3x^2 - 2x + 1}{p} \right) \right] = p - 2 \left( \frac{-3x^2 - 2x + 1}{p} \right).$$
(3.23)

Then, we use Lemma 2.4 again. The discriminant now equals to 4-4(-3)1 = 16. For  $p \ge 5$ , p does not divide discriminant, so the sum is  $-\left(\frac{-3}{p}\right)$ .

For  $x \neq 0, -1$ , the number of solutions to  $x^2 + xy + x + y^2 + y \equiv 0$  is  $p - 2 - \left(\frac{-3}{p}\right)$ ; the number of solutions to  $x - y \equiv 0$  is at most p - 2. At most two pairs of (x, y) satisfy both  $x^2 + xy + x + y^2 + y \equiv 0$  and x = y. There are no pairs that satisfy  $3x^2 \equiv -2x$ , so we do not have over-counting. Thus, the total number of pairs is

$$2p - 2 - \left(\frac{-3}{p}\right). \tag{3.24}$$

When  $\delta(x, y) \neq 0$  and  $x = y \neq 0, -1$ , clearly  $\left(\frac{(x^3 + x^2)(y^3 + y^2)}{p}\right)$  contributes 1.

Consider  $x \neq y$  and  $x^2 + xy + x + y^2 + y \equiv 0$  and  $x, y \neq 0, -1$ . Then,  $y^2 + y \equiv -x(x+y+1)$ and  $x^2 + x \equiv -y(y+x+1)$  and

$$\left(\frac{(x^3+x^2)(y^3+y^2)}{p}\right) = \left(\frac{x(x^2+x)y(y^2+y)}{p}\right) = \left(\frac{x^2y^2(x+y+1)}{p}\right).$$
(3.25)

As long as  $x \neq -y - 1$ , the contribution is 1. If x = -y - 1, then we will have  $x^2 + x \equiv 0$ . This implies x = 0, -1, which can not happen since  $x, y \neq 0, -1$ . Therefore, all pairs have their Legendre factor +1, and we need only count how many such pairs are there:

$$pA_{2,\mathcal{F}}(p) = p\left[2p - 2 - \left(\frac{-3}{p}\right)\right] - \sum_{x,y\neq 0,-1} \left(\frac{(x^3 + x^2)(y^3 + y^2)}{p}\right) - p^2$$
$$= p^2 - 2p - \left(\frac{-3}{p}\right)p - 1.$$
(3.26)

**3.2.2**  $y^2 = x^3 + tx^2 + x + 1$ 

**Lemma 3.7.** The first moment of the one-parameter family  $y^2 = x^3 + tx^2 + x + 1$  is -1, and the family's rank is 1.

Proof.

$$-pA_{1,\mathcal{F}}(p) = -\sum_{t(p)} a_{t(p)} = \sum_{t(p)} \sum_{x(p)} \left( \frac{x^3 + x^2(t+1) + x + 1}{p} \right)$$
$$= \sum_{x=1}^{p-1} \sum_{t(p)} \left( \frac{x^3 + tx^2 + x + 1}{p} \right) + \sum_{t(p)} \left( \frac{1}{p} \right)$$
$$= 0 + p$$
$$= p$$
(3.27)

**Lemma 3.8.** The second moment of the one-parameter family  $y^2 = x^3 + tx^2 + x + 1$  times p is  $p^2 - p - 1 + p \sum_{x(p)} \left(\frac{4x^3 + x^2 + 2x + 1}{p}\right)$ , which supports our Bias Conjecture.

*Proof.* We compute the second moment using Gauss Sum Expansion (Lemma 2.6):

$$pA_{2,\mathcal{F}}(p) = \sum_{t(p)} a_t^{2}(p)$$

$$= \sum_{t(p)} \sum_{x(p)} \sum_{y(p)} \left(\frac{x^3 + x + 1 + x^2t}{p}\right) \left(\frac{y^3 + y + 1 + y^2t}{p}\right)$$

$$= \sum_{x,y(p)} \sum_{c,d=1}^{p-1} \frac{1}{p} \left(\frac{cd}{p}\right) \mathbf{e} \left(\frac{c(x^3 + x + 1) - d(y^3 + y + 1)}{p}\right) \sum_{t(p)} \mathbf{e} \left(\frac{(cx^2 - dy^2)t}{p}\right).$$
(3.28)

Note that c and d are invertible mod p. If the numerator in the *t*-exponential is non-zero, the *t*-sum vanishes. If exactly one of x and y vanishes, the numerator is not congruent to zero mod p. Hence, either or neither are zero. If both are zero, the *t*-sum gives p, the *c*-sum gives  $G_p$ , the *d*-sum gives  $(G_p)^{-1}$ , for a total contribution of p.

Assume x and y are non-zero. Then  $d = cx^2y^{-2}$  (otherwise the t-sum is zero). The t-sum yields p, and we have:

$$pA_{2,\mathcal{F}}(p) = \sum_{x,y=1}^{p-1} \sum_{c=1}^{p-1} \frac{1}{p} \left( \frac{x^2 y^2}{p} \right) \mathbf{e} \left( \frac{cy^{-2} (x^3 y^2 + xy^2 + y^2 - x^2 y^3 - x^2 y - x^2)}{p} \right) p + p$$
$$= \sum_{x,y=1}^{p-1} \sum_{c=1}^{p-1} \left( \frac{x^2 y^2}{p} \right) \mathbf{e} \left( \frac{cy^{-2} (x - y) (x^2 y^2 - xy - x - y)}{p} \right) + p$$

$$=\sum_{x,y=1}^{p-1}\sum_{c=0}^{p-1} \left(\frac{x^2y^2}{p}\right) \mathbf{e}\left(\frac{cy^{-2}(x-y)(x^2y^2-xy-x-y)}{p}\right) + p - \sum_{x,y=1}^{p-1} \left(\frac{x^2y^2}{p}\right)$$
$$=\sum_{x,y=1}^{p-1}\sum_{c=0}^{p-1} \mathbf{e}\left(\frac{cy^{-2}(x-y)(x^2y^2-xy-x-y)}{p}\right) + p - (p-1)^2.$$
(3.29)

If  $g(x,y) = (x-y)(x^2y^2 - xy - x - y \equiv 0(p))$ , then the *c*-sum is *p*, otherwise it is 0. We are left with counting how often  $g(x,y) \equiv 0$  for x, y non-zero.

Clearly, whenever x = y,  $g(x, y) \equiv 0(p)$ . There are p - 1 solutions for each non-zero x, so the total contribution is p(p-1).

Consider  $x^2y^2 - xy - x - y \equiv 0$  now. By the Quadratic Formula mod p,

$$y = \frac{(x+1) \pm \sqrt{(x+1)^2 + 4x^3}}{2x^2}$$
  
=  $\frac{(x+1) \pm \sqrt{4x^3 + x^2 + 2x + 1}}{2x^2}$ . (3.30)

If  $4x^3 + x^2 + 2x + 1$  is a non-zero square, y has two distinct values. If it equals to 0, y has one value, and if it does not equal to a square, y does not have a value.

For a given non-zero x, the number of non-zero y for  $4x^3 + x^2 + 2x + 1$  is  $1 + \left(\frac{4x^3 + x^2 + 2x + 1}{p}\right)$ . Hence the number of non-zero pairs with  $4x^3 + x^2 + 2x + 1$  is

$$\sum_{x \neq 0} \left( 1 + \left( \frac{4x^3 + x^2 + 2x + 1}{p} \right) \right) = p - 1 + \sum_{x=0}^p \left( \frac{4x^3 + x^2 + 2x + 1}{p} \right) - 1.$$
(3.31)

Each of these pairs contributes p, so the total contribution is

$$p^{2} + p \sum_{x} \left( \frac{4x^{3} + x^{2} + 2x + 1}{p} \right) - 2p.$$
(3.32)

We must be careful about double counting. If both  $x - y \equiv 0$  and  $x^2y^2 - xy - x - y \equiv 0$ , then we find  $x^3 \equiv x + 2$   $(x \neq 0)$ , and we have one double-counted solution.

Therefore, the second moment times p equals to:

$$pA_{2,\mathcal{F}}(p) = p^2 + p\left(\sum_{x(p)} \left(\frac{4x^3 + x^2 + 2x + 1}{p}\right)\right) - 2p - p + p(p-1) + p - (p-1)^2$$
$$= p^2 - p - 1 + p\sum_{x(p)} \left(\frac{4x^3 + x^2 + 2x + 1}{p}\right).$$
(3.33)

Although we have a  $p^{3/2}$  term in the second moment, by the Sato-Tate conjecture (which has been proven by Taylor, jointly with Clozel, Harris and Shepherd Barron, see [Clo]) this will have a mean of zero because it is p times the coefficients of an elliptic curve  $\mathcal{E}: y^2 = 4x^3 + x^2 + 2x + 1$ . Hence, the Bias Conjecture still holds.

**3.2.3** 
$$y^2 = x^3 + tx^2 + tx + t^2$$

**Lemma 3.9.** The first moment of the one-parameter family  $y^2 = x^3 + tx^2 + tx + t^2$  is -1, and the family's rank is 1.

Proof.

$$-pA_{1,\mathcal{F}}(p) = -\sum_{t(p)} a_{t(p)} = \sum_{t(p)} \sum_{x(p)} \left( \frac{x^3 + tx^2 + tx + t^2}{p} \right)$$

$$= \sum_{t=1}^{p-1} \sum_{x(p)} \left( \frac{x^3 + tx^2 + tx + t^2}{p} \right)$$

$$= \sum_{t=1}^{p-1} \sum_{x(p)} \left( \frac{t^3 x^3 + t^3 x^2 + t^2 x + t^2}{p} \right)$$

$$= \sum_{t=1}^{p-1} \sum_{x(p)} \left( \frac{t^2}{p} \right) \left( \frac{tx^3 + tx^2 + x + 1}{p} \right)$$

$$= \sum_{t=0}^{p-1} \sum_{x(p)} \left( \frac{t(x^3 + x^2) + x + 1}{p} \right) - \sum_{x(p)} \left( \frac{x + 1}{p} \right)$$

$$= \sum_{t(p)} \sum_{x=0,-1} \left( \frac{t(x^3 + x^2) + x + 1}{p} \right) + \sum_{t(p)} \sum_{x(p)x\neq 0,-1} \left( \frac{t(x^3 + x^2) + x + 1}{p} \right) - 0$$

$$= \sum_{t(p)} \sum_{x=-1} \left( \frac{0}{p} \right) + \sum_{t(p)} \sum_{x=0} \left( \frac{1}{p} \right) + \sum_{x(p)x\neq 0,-1} \sum_{t(p)} \left( \frac{t + x + 1}{p} \right)$$

$$= 0 + p + 0 = p$$
(3.34)

**Lemma 3.10.** The second moment of the one-parameter family  $y^2 = x^3 + tx^2 + tx + t^2$  times p is  $p^2 - 3p - 1$  if p is 1 mod 4 and  $p^2 - p - 1$  if p is 3 mod 4 which supports our Bias Conjecture.

Proof.

$$pA_{2,\mathcal{F}}(p) = \sum_{t(p)} a_t^2(p)$$
$$= \sum_{t(p)} \sum_{x(p)} \sum_{y(p)} \left( \frac{tx^2 + tx + t^2 + x^3}{p} \right) \left( \frac{ty^2 + ty + t^2 + y^3}{p} \right)$$

$$=\sum_{t=1}^{p-1}\sum_{x,y(p)} \left(\frac{t^3x^2 + t^2x + t^2 + t^3x^3}{p}\right) \left(\frac{t^3y^2 + t^2y + t^2 + t^3y^3}{p}\right)$$

$$=\sum_{t=1}^{p-1}\sum_{x,y(p)} \left(\frac{t^4}{p}\right) \left(\frac{t(x^3 + x^2) + x + 1}{p}\right) \left(\frac{t(y^3 + y^2) + y + 1}{p}\right)$$

$$=\sum_{t=0}^{p-1}\sum_{x,y(p)} \left(\frac{t(x^3 + x^2) + x + 1}{p}\right) \left(\frac{t(y^3 + y^2) + y + 1}{p}\right) - \sum_{x,y(p)} \left(\frac{x + 1}{p}\right) \left(\frac{y + 1}{p}\right)$$

$$=\sum_{t(p)}\sum_{x,y(p)} \left(\frac{t(x^3 + x^2) + x + 1}{p}\right) \left(\frac{t(y^3 + y^2) + y + 1}{p}\right) - 0$$

$$=\sum_{t(p)}\sum_{x,y(p)} \left(\frac{t(x^3 + x^2) + x + 1}{p}\right) \left(\frac{t(y^3 + y^2) + y + 1}{p}\right)$$
(3.35)

We have

$$a = (x^{3} + x^{2})(y^{3} + y^{2})$$
  

$$b = (x^{3} + x^{2})(y + 1) + (y^{3} + y^{2})(x + 1)$$
  

$$c = (x + 1)(y + 1)$$
  

$$\delta = b^{2} - 4ac = [(x^{3} + x^{2})(y + 1) - (y^{3} + y^{2})(x + 1)]^{2}.$$
  
(3.36)

The discriminant  $\delta(x,y)$  can be rewritten as

$$\delta(x,y) = (x-y)(x+y)(x+1)(y+1).$$
(3.37)

The only way that makes  $(x^3 + x^2)(y + 1)$  or  $(y^3 + y^2)(x + 1)$  vanish is when x and y both equal to -1. Therefore,

$$pA_{2,\mathcal{F}}(p) = \sum_{x,y\neq 0,-1;\delta(x,y)\equiv 0} p\left(\frac{(x^3+x^2)(y+1)-(y^3+y^2)(x+1)}{p}\right) - \sum_{x,y\neq 0,-1} \left(\frac{(x^3+x^2)(y+1)-(y^3+y^2)(x+1)}{p}\right) - 1. \quad (3.38)$$

We can see that  $\delta(x, y) \equiv 0$  if x = y and this happens p - 2 times. If x = y then the second factor equals to  $2x^3 + 3x^2 + 2x$ , which is congruent to zero at most three times.

By the Quadratic Formula mod p (Lemma 2.4),  $\delta_2(x, y) = x^2y + x^2 + xy^2 + 2xy + x + y^2 + y \equiv 0(p)$  when

$$y = \frac{-(x^2 + 2x + 1) \pm \sqrt{x^4 - 2x + 1}}{2(x+1)}$$

$$= \frac{-(x^2 + 2x + 1) \pm \sqrt{(x+1)^2(x-1)^2}}{2(x+1)},$$
(3.39)

which reduces to find when  $(x + 1)^2(x - 1)^2$  is a square mod p. We get 2 distinct values of y if it is equivalent to a non-zero square, 1 value if it equals to 0, and no value if it does not equal to a square. We can see that  $x^4 - 2x + 1$  is always a square unless x = 1 and x = -1. Since we already state that x can not equal to -1, so we only need to deal with x = 1. Thus, the number of solutions  $\delta_2 \equiv 0(p)$  is (p-2), and the total contribution is p(p-2).

Therefore, on average p times the second moment equals to

$$pA_{2,\mathcal{F}}(p) = p(p-2) - \sum_{x,y\neq 0,-1} \left( \frac{(x^3 + x^2)(y+1) - (y^3 + y^2)(x+1)}{p} \right) - 1$$
  
=  $p^2 - 2p - 1.$  (3.40)

Keep in mind that we have three kinds of primes: when p = 2 (this case is trivial in the computations we have in this paper), when  $p \equiv 1 \mod 4$  and when  $p \equiv 3 \mod 4$ . When x = y and x = -y, can both help the discriminant to vanish. If  $x = y \neq 0$ , then  $\left(\frac{x}{p}\right)\left(\frac{y}{p}\right) = \left(\frac{x^2}{p}\right)$  and every prime always contributes p; if  $p \equiv 1 \mod 4$  and  $x = -y \neq 0$ , by Dirichlet's theorem for primes in arithmetic progression (Lemma 2.5)  $\left(\frac{x}{p}\right)\left(\frac{-y}{p}\right) = \left(\frac{-1}{p}\right)\left(\frac{x^2}{p}\right) = \left(\frac{x^2}{p}\right)$  also contributes p. If  $p \equiv 1 \mod 4$  and x = -y, by Dirichlet's theorem for primes in arithmetic progression there should be an extra contribution of p. However, since we already count the contribution from x = -y, we need to subtract p from the average second moment:

$$pA_{2,\mathcal{F}}(p) = p^2 - 2p - 1 - p$$
  
=  $p^2 - 3p - 1.$  (3.41)

If  $p \equiv 3 \mod 4$  and x = -y, by Dirichlet's theorem for primes in arithmetic progression (Lemma 2.5) there should be an extra contribution of -p. However, since we already count the contribution from x = -y, we need to subtract -p from the average second moment:

$$pA_{2,\mathcal{F}}(p) = p^2 - 2p - 1 - (-p)$$
  
=  $p^2 - p - 1.$  (2.42)

(3.42)

Now we move on to construct some rank 2 families.

#### 3.3 Construction of Rank 2 Families

**3.3.1** 
$$y^2 = x^3 - x^2 + (x^2 - x)t + 1$$

**Lemma 3.11.** The first moment of the one-parameter family  $y^2 = x^3 - x^2 + (x^2 - x)t + 1$  is -2, and the family's rank is 2.

Proof.

$$-pA_{1,\mathcal{F}}(p) = -\sum_{t(p)} a_{t(p)} = \sum_{t(p)} \sum_{x(p)} \left( \frac{x^3 - x^2 + (x^2 - x)t + 1}{p} \right)$$
$$= \sum_{x=0}^{p-1} \sum_{t=0}^{p-1} \left( \frac{(x^2 - x)t + (x^3 - x^2 + 1)}{p} \right)$$
$$= \sum_{x\neq 0,1} \sum_{t=0}^{p-1} \left( \frac{t + (x^3 - x^2 + 1)}{p} \right) + \sum_{t=0}^{p-1} \left[ \left( \frac{1}{p} \right) + \left( \frac{1}{p} \right) \right]$$
$$= 0 + 2p$$
$$= 2p$$
(3.43)

We apply linear Legendre sums to  $\sum_{t=0}^{p-1} \left( \frac{(x^2-x)t+(x^3-x^2+1)}{p} \right)$ . If x = 0, 1, we have two  $\sum_{t(p)} \left( \frac{1}{p} \right)$ , so the rank equals to 2.

**Conjecture 3.12.** We conjecture that the second moment of the one-parameter family  $y^2 = x^3 - x^2 + (x^2 - x)t + 1$  times p is  $p^2 - 1$  on average, which supports our Bias Conjecture.

We are not able to prove the second moment of this family theoretically, so we observe numerically and generate the second moment form for the first 100 primes:

We can see that for the first 100 primes, every form has  $p^2 - c_1p - 1$  (see Appendix C.1) for the complete data table). The second moment  $c_1$  is always less than  $2\sqrt{p}$  in absolute value. This is important because otherwise, the count is not for an elliptic curve. What's more,  $c_1$  seems to be even numbers and grow, but the sum of  $c_1$ s seems to average to zero. We conjecture that the form of this one-parameter family is  $p^2 - 1$  on average, but there might be terms of 1,  $p^{1/2}$ , p, or  $p^{3/2}$ . This family is a potential counterexample to a stronger form of Miller's Conjecture based on the families studied to date, which is that the first term that does not average to zero is the p term and that has a negative average.

### **3.3.2** $y^2 = x^3 - x + t^4$

**Conjecture 3.13.** We conjecture that the first moment of the one-parameter family  $y^2 = x^3 - x + t^4$  is -2 on average, and the family's rank is 2 on average.

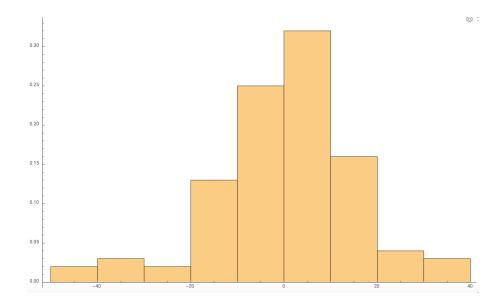

Figure 8: The distribution of the largest lower order term in the second moment expansion of  $y^2 = x^3 - x^2 + (x^2 - x)t + 1$  for the first 100 primes.

We are not able to prove the first moment of this family theoretically, so we observe numerically and generate the first moment form for the first 100 primes:

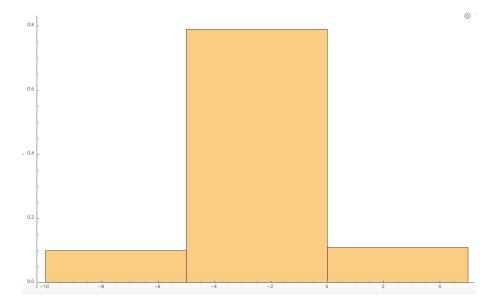

Figure 9: The distribution of the first moment of  $y^2 = x^3 - x + t^4$  for the first 100 primes.

We can see that -2 appears frequently, but there are some 2 and -6 (see Appendix C.2 for the complete data table). We conjecture that the first moment is -2 on average and the rank of this family is 2 on average.

**Conjecture 3.14.** We conjecture that the second moment of the one-parameter family  $y^2 = x^3 - x + t^4$  times p is  $p^2 - p$  on average, which supports our Bias Conjecture.

We are not able to prove the second moment of this family theoretically, so we observe

numerically and generate the second moment form for the first 100 primes:

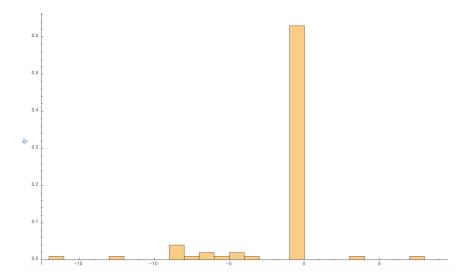

Figure 10: The distribution of the largest lower order term in the second moment expansion of  $y^2 = x^3 - x + t^4$  for the first 100 primes.

We can see that for the first 100 primes,  $p^2 - p$  appears most of the times (see Appendix C.3). We observe that primes that are 5 mod 8 do not have a constant term. Primes that are 3 mod 4 always have the form of  $p^2 - p$  (although some 1 mod 4 primes have it too). However, we are not able to compute the exact second form times p. We conjecture the form times p to be  $p^2 - p$  on average, but there might be terms of 1,  $p^{1/2}$ , p or  $p^{3/2}$ .

Now we turn to see if the Bias Conjecture holds in some two-parameter families.

## 4 Biases in First and Second Moments in Two-Parameter Families

In this section, we are going to compute the biases in first and second moments in twoparameter families. As mentioned before the representative calculation, we do not have a closed form for cubic and higher degree of Legendre sums. In the case of our two-parameter families, we unfortunately are going to have cubic and higher degree of Legendre sums. However, by cleverly writing s in terms of t, we get linear and quadratic Legendre sums and calculate them using closed form. Then, we count the number of ways the discriminant of this new closed form vanishes, or equals to 0, because these pairs contribute a Legendre factor of +1. Keep in mind that for two-parameter families, Rosen-Silverman does not hold in them so the ranks are conjectural. Checking their ranks is beyond the scope of this paper. See [WAZ] for more details.

### 4.1 Construction of Rank 0 Families

**4.1.1**  $y^2 = x^3 + tx + sx^2$ 

**Lemma 4.1.** The first moment of the two-parameter family  $y^2 = x^3 + tx + sx^2$  is 0.

Proof.

$$-p^{2}A_{1,\mathcal{F}}(p) = -\sum_{t(p)}\sum_{s(p)}a_{t,s}(p) = \sum_{t(p)}\sum_{s(p)}\sum_{s(p)}\left(\frac{x^{3} + tx + sx^{2}}{p}\right)$$

$$=\sum_{t=1}^{p-1}\sum_{x(p)}\sum_{s(p)}\left(\frac{t^{3}x^{3} + t^{2}x + st^{2}x^{2}}{p}\right)$$

$$=\sum_{t=1}^{p-1}\sum_{x(p)}\sum_{s(p)}\left(\frac{tx^{3}}{p}\right)\left(\frac{tx^{3} + x + sx^{2}}{p}\right)$$

$$=\sum_{t(p)}\sum_{x(p)}\sum_{s(p)}\left(\frac{tx^{3} + x + sx^{2}}{p}\right) - \sum_{x(p)}\sum_{s(p)}\left(\frac{x + sx^{2}}{p}\right)$$

$$=\sum_{x(p)}\sum_{s(p)}\sum_{t(p)}\left(\frac{tx^{3} + sx^{2} + x}{p}\right) - 0$$

$$=\sum_{x(p)}\sum_{s(p)}\sum_{t=0}\left(\frac{sx^{2} + x}{p}\right) + \sum_{x(p)}\sum_{s(p)}\sum_{t(p), t\neq 0}\left(\frac{tx^{3} + x + sx^{2}}{p}\right)$$

$$+\sum_{x(p)}\sum_{t(p)}\sum_{s=0}\left(\frac{tx^{3} + x}{p}\right) + \sum_{x(p)}\sum_{s(p)}\sum_{t(p), s\neq 0}\left(\frac{tx^{3} + x + sx^{2}}{p}\right) - 0$$

$$=0$$

$$=0$$

$$(4.1)$$

**Lemma 4.2.** The second moment of the two-parameter family  $y^2 = x^3 + tx + sx^2$  times  $p^2$  is  $p^3 - 2p^2 + p$ , which supports our Bias Conjecture.

Proof.

$$p^{2}A_{2,\mathcal{F}}(p) = \sum_{t,s(p)} a_{t,s}^{2}(p)$$

$$= \sum_{t(p)} \sum_{s(p)} \sum_{x,y(p)} \left(\frac{x^{3} + tx + sx^{2}}{p}\right) \left(\frac{y^{3} + ty + sy^{2}}{p}\right)$$

$$= \sum_{t=1}^{p-1} \sum_{s(p)} \sum_{x,y(p)} \left(\frac{x^{3} + tx + sx^{2}}{p}\right) \left(\frac{y^{3} + ty + sy^{2}}{p}\right)$$

$$= \sum_{t=1}^{p-1} \sum_{s(p)} \sum_{x,y(p)} \left(\frac{t^{3}x^{3} + t^{2}x + st^{2}x^{2}}{p}\right) \left(\frac{t^{3}y^{3} + t^{2}y + st^{2}y^{2}}{p}\right)$$

$$= \sum_{t=1}^{p-1} \sum_{s(p)} \sum_{x,y(p)} \left(\frac{t^4}{p}\right) \left(\frac{tx^3 + x + sx^2}{p}\right) \left(\frac{ty^3 + y + sy^2}{p}\right)$$

$$= \sum_{t=0}^{p-1} \sum_{s(p)} \sum_{x,y(p)} \sum_{x,y(p)} \left(\frac{tx^3 + x + sx^2}{p}\right) \left(\frac{ty^3 + y + sy^2}{p}\right) - \sum_{s(p)} \sum_{x,y(p)} \sum_{x,y(p)} \left(\frac{tx^3 + x + sx^2}{p}\right) \left(\frac{ty^3 + y + sy^2}{p}\right) - (p-1)$$

$$= \sum_{x,y(p)} \sum_{s(p)} \sum_{t(p)} \left(\frac{tx^3 + x + sx^2}{p}\right) \left(\frac{ty^3 + y + sy^2}{p}\right) - (p-1)$$
(4.2)

We compute the discriminant of the equation in terms of t and s:

$$a = x^{3}y^{3}$$

$$b = x^{3}(y + sy^{2}) + y^{3}(x + sx^{2})$$

$$c = (y + sy^{2})(x + sx^{2})$$

$$\delta = b^{2} - 4ac = [(x^{3}(y + sy^{2}) - y^{3}(x + sx^{2})]^{2}$$

$$= [xy(x - y)(sxy + x + y)]^{2}.$$
(4.3)

We need to count the number of times x, y and s vanish. Let us consider xy(x - y) first. When x = 0, y can be any number except 0 because we have x = y = 0 later when  $x - y \equiv 0(p)$ . We can also see that s vanishes, so the contribution from x = 0 is p - 1. Similarly, when y = 0, its contribution is p - 1. When  $x = y \neq 0, x - y \equiv 0(p)$  and s does not vanish. We have a special case when x = y = 0 and its contribution is 1. The total contribution from  $x - y \equiv 0(p)$ is p(p - 1) + 1.

Then, we consider sxy + x + y. When  $s \equiv 0(p)$ , we are left with x + y. The contribution from  $x + y \equiv 0(p)$  is  $(p-1)^2$ . When  $s \not\equiv 0(p)$ , the contribution from  $s + x + y \equiv 0(p)$  is  $(p-1)^3$ . We need to be careful about double-counting. If x = y and sxy + x + y are both congruent to zero mod p, then we have  $sx^2 + 2x \equiv 0(p)$ . Every s has 1 corresponding x value, so we overcount by  $p^2$ .

Therefore, the second moment equals to:

$$p^{2}A_{2,\mathcal{F}}(p) = (p-1) + (p-1) + (p-1)p + 1 + (p-1)^{2} + (p-1)^{3} - p^{2} - (p-1)$$
$$= p^{3} - 2p^{2} + p.$$

(4.4)

**4.1.2**  $y^2 = x^3 + t^2x + st^4$ 

**Lemma 4.3.** The first moment of the two-parameter family  $y^2 = x^3 + t^2x + st^4$  is 0.

Proof.

$$p^{2}A_{1,\mathcal{F}}(p) = -\sum_{t(p)} \sum_{s(p)} a_{t,s}(p) = \sum_{t(p)} \sum_{x(p)} \sum_{s(p)} \left(\frac{x^{3} + t^{2}x + st^{4}}{p}\right)$$

$$= \sum_{t=1}^{p-1} \sum_{x(p)} \sum_{s(p)} \left(\frac{t^{3}x^{3} + t^{3}x + st^{4}}{p}\right)$$

$$= \sum_{t=1}^{p-1} \sum_{x(p)} \sum_{s(p)} \left(\frac{t^{3}}{p}\right) \left(\frac{x^{3} + x + st}{p}\right)$$

$$= \sum_{x(p)} \sum_{s(p)} \sum_{t(p)} \left(\frac{t}{p}\right) \left(\frac{st + (x^{3} + x)}{p}\right)$$

$$= \sum_{x(p)} \sum_{s(p)} \sum_{t(p)} \left(\frac{t}{p}\right) \left(\frac{t^{-1}st + (x^{3} + x)}{p}\right)$$

$$= \sum_{x(p)} \sum_{s(p)} \sum_{t(p)} \left(\frac{t}{p}\right) \left(\frac{s + (x^{3} + x)}{p}\right).$$
(4.5)

Since t is not zero, we send s to  $t^{-1}s$ , and look at the s sum, which equals to zero.

**Lemma 4.4.** The second moment times  $p^2$  of the two-parameter family  $y^2 = x^3 + t^2x + st^4$  is  $p^3 - 2p^2 + p - 2(p^2 - p)(\frac{-3}{p})$ , which supports our Bias Conjecture.

*Proof.* We have

$$\begin{split} p^2 A_{2,\mathcal{F}}(p) &= \sum_{t,s(p)} a_{t,s}^2(p) \\ &= \sum_{t(p)} \sum_{s(p)} \sum_{x,y(p)} \left( \frac{x^3 + t^2 x + st^4}{p} \right) \left( \frac{y^3 + t^2 y + st^4}{p} \right) \\ &= \sum_{t=1}^{p-1} \sum_{s(p)} \sum_{x,y(p)} \left( \frac{t^3 x^3 + t^3 x + st^4}{p} \right) \left( \frac{t^3 y^3 + t^3 y + st^4}{p} \right) \\ &= \sum_{t=1}^{p-1} \sum_{s(p)} \sum_{x,y(p)} \left( \frac{t^6}{p} \right) \left( \frac{x^3 + x + st}{p} \right) \left( \frac{y^3 + y + st}{p} \right) \\ &= \sum_{t=0}^{p-1} \sum_{s(p)} \sum_{x,y(p)} \left( \frac{x^3 + x + st}{p} \right) \left( \frac{y^3 + y + st}{p} \right) - \sum_{s(p)} \sum_{x,y(p)} \left( \frac{x^3 + x}{p} \right) \left( \frac{y^3 + y}{p} \right) \\ &= \sum_{x,y(p)} \sum_{s(p)} \sum_{t(p)} \left( \frac{st + (x^3 + x)}{p} \right) \left( \frac{st + (y^3 + y)}{p} \right) - p \left[ \sum_{x(p)} \left( \frac{x^3 + x}{p} \right) \right]^2 \\ &= \sum_{s=0} \sum_{t(p)} \left[ \sum_{x(p)} \left( \frac{x^3 + x}{p} \right) \right]^2 + \sum_{x,y(p)} \sum_{s \neq 0} \sum_{t(p)} \left( \frac{st + (x^3 + x)}{p} \right) \left( \frac{st + (y^3 + y)}{p} \right) \\ &= \sum_{s=0} \sum_{t(p)} \left[ \sum_{x(p)} \left( \frac{x^3 + x}{p} \right) \right]^2 + \sum_{x,y(p)} \sum_{s \neq 0} \sum_{t(p)} \left( \frac{st + (x^3 + x)}{p} \right) \left( \frac{st + (y^3 + y)}{p} \right) \\ &= \sum_{s=0} \sum_{t(p)} \left[ \sum_{x(p)} \left( \frac{x^3 + x}{p} \right) \right]^2 + \sum_{x,y(p)} \sum_{s \neq 0} \sum_{t(p)} \left( \frac{st + (x^3 + x)}{p} \right) \left( \frac{st + (y^3 + y)}{p} \right) \\ &= \sum_{s=0} \sum_{t(p)} \left[ \sum_{x(p)} \left( \frac{x^3 + x}{p} \right) \right]^2 \\ &= \sum_{s=0} \sum_{t(p)} \left[ \sum_{x(p)} \left( \frac{x^3 + x}{p} \right) \right]^2 \\ &= \sum_{x,y(p)} \sum_{s \neq 0} \sum_{t(p)} \left[ \sum_{x(p)} \left( \frac{x^3 + x}{p} \right) \right]^2 \\ &= \sum_{x,y(p)} \sum_{s \neq 0} \sum_{t(p)} \left[ \sum_{x(p)} \left( \frac{x^3 + x}{p} \right) \right]^2 \\ &= \sum_{x,y(p)} \sum_{t(p)} \sum_{t(p)} \left[ \sum_{x(p)} \left( \frac{x^3 + x}{p} \right) \right]^2 \\ &= \sum_{t(p)} \sum_{t(p)} \left[ \sum_{x(p)} \left( \frac{x^3 + x}{p} \right) \right]^2 \\ &= \sum_{t(p)} \sum_{t(p)} \left[ \sum_{x(p)} \left( \frac{x^3 + x}{p} \right) \right]^2 \\ &= \sum_{t(p)} \sum_{t(p)} \left[ \sum_{x(p)} \left( \frac{x^3 + x}{p} \right) \right]^2 \\ &= \sum_{t(p)} \sum_{t(p)} \left[ \sum_{x(p)} \left( \frac{x^3 + x}{p} \right) \right]^2 \\ &= \sum_{t(p)} \sum_{t(p)} \left[ \sum_{x(p)} \left( \frac{x^3 + x}{p} \right] \\ &= \sum_{t(p)} \sum_{t(p)} \left[ \sum_{t(p)} \left( \frac{x^3 + x}{p} \right) \right]^2 \\ &= \sum_{t(p)} \sum_{t(p)} \left[ \sum_{t(p)} \left( \frac{x^3 + x}{p} \right) \right]^2 \\ &= \sum_{t(p)} \sum_{t(p)} \sum_{t(p)} \left[ \sum_{t(p)} \left( \frac{x^3 + x}{p} \right) \right]^2 \\ &= \sum_{t(p)} \sum_{t(p)} \sum_{t(p)} \sum_{t(p)} \left[ \sum_{t(p)} \left( \frac{x^3 + x}{p} \right) \right]^2 \\ &= \sum_{t(p)} \sum_{t(p)} \sum_{t(p)} \sum_{t(p)} \left[ \sum_{t(p)} \left( \frac{x^3 + x}{p} \right] \\ &=$$

$$-p\left[\sum_{x(p)} \left(\frac{x^{3}+x}{p}\right)\right]^{2}$$

$$=\sum_{x,y(p)} \sum_{s\neq 0} \sum_{t(p)} \left(\frac{st+(x^{3}+x)}{p}\right) \left(\frac{st+(y^{3}+y)}{p}\right)$$

$$=\sum_{x,y(p)} \sum_{s\neq 0} \sum_{t(p)} \left(\frac{ss^{-1}t+(x^{3}+x)}{p}\right) \left(\frac{ss^{-1}t+(y^{3}+y)}{p}\right)$$

$$=\sum_{x,y(p)} \sum_{s\neq 0} \sum_{t(p)} \left(\frac{t+(x^{3}+x)}{p}\right) \left(\frac{t+(y^{3}+y)}{p}\right)$$

$$=(p-1) \sum_{x,y(p)} \sum_{t(p)} \left(\frac{t+(x^{3}+x)}{p}\right) \left(\frac{t+(y^{3}+y)}{p}\right),$$
(4.6)

where in passing from the second to the third line we sent x and y modulo p to tx and ty, which is valid so long as t is not zero; to keep the sum over all t we need to subtract the t = 0contribution. We can also see that when s = 0, since the t-sum is p and there is no t dependence, the contribution from s = 0 and t = 0 cancel out each other. Note that now as s is non-zero, we can send t to  $s^{-1}t$ , and we get a nice quadratic sum in t.

We use Lemma 2.3. The discriminant of our quadratic in t equals

$$a = 1$$
  

$$b = (x^{3} + x) + (y^{3} + y)$$
  

$$c = (x^{3} + x)(y^{3} + y)$$
  

$$\delta(x, y) = b^{2} - 4ac = [(x^{3} + x) - (y^{3} + y)]^{2}$$
  

$$= [(x - y)(y^{2} + xy + (1 + x^{2}))]^{2}, \qquad (4.7)$$

and we are going to count the number of ways it vanishes. Therefore,

$$p^{2}A_{2,\mathcal{F}}(p) = (p-1) \left[ \sum_{\substack{x,y \mod p \\ \delta(x,y) \equiv 0(p)}} \sum_{t(p)} \left( \frac{t + (x^{3} + x)}{p} \right) \left( \frac{t + (y^{3} + y)}{p} \right) + \sum_{\substack{x,y \mod p \\ \delta(x,y) \neq 0(p)}} \sum_{t(p)} \left( \frac{t + (x^{3} + x)}{p} \right) \left( \frac{t + (y^{3} + y)}{p} \right) \right]$$

$$= (p-1) \left[ \sum_{\substack{x,y \mod p \\ \delta(x,y) \equiv 0(p)}} (p-1) + \sum_{\substack{x,y \mod p \\ \delta(x,y) \neq 0(p)}} (-1) \right]$$
$$= (p-1) \left[ p \sum_{\substack{x,y \mod p \\ \delta(x,y) \equiv 0(p)}} + p^{2}(-1) \right].$$
(4.8)

We have three cases for  $\delta(x, y) \equiv 0(p)$ .

Case 1: We need to count the number of solutions of  $\delta_1(x, y) = x - y \equiv 0$ , which happens p times when x = y.

Case 2: We need to count the number of solutions of  $\delta_2(x, y) = y^2 + xy + (1 + x^2) \equiv 0$ . By the Quadratic Formula mod p, we have

$$y = \frac{-x \pm \sqrt{-3x^2 - 4}}{2},\tag{4.9}$$

which reduced to finding when  $-3x^2 - 4$  is a square. Thus, summing over x for p > 2 yields

$$\sum_{x(p)} \left[ 1 + \left( \frac{-3x^2 - 4}{p} \right) \right] = p + \sum_{x(p)} \left( \frac{-3x^2 - 4}{p} \right)$$
$$= p - \left( \frac{-3}{p} \right), \tag{4.10}$$

which follows from Lemma 2.3. The discriminant now is  $0^2 - 4 \cdot (-3) \cdot (-4)$ . For  $p \ge 5$ , p does not divide the discriminant, hence this sum is  $p - \left(\frac{-3}{p}\right)$ .

Case 3: We need to be careful about double-counting. The double-counted pairs satisfy both x = y and  $y^2 + xy + (1 + x^2) \equiv 0(p)$ , which means that they satisfy  $3x^2 + 1 \equiv 0(p)$ , or  $-3x^2 \equiv 1$ . Thus, there is a double-counted solution if and only if  $\left(\frac{-3}{p}\right) = 1$ , and the number of double-counted pairs is  $1 + \left(\frac{-3}{p}\right)$ .

Therefore, the total number of pairs for  $\delta(x, y) \equiv 0(p)$  is:

$$\sum_{\delta_1(x,y)\equiv 0} + \sum_{\delta_2(x,y)\equiv 0} -\sum_{\delta_1(x,y)\equiv 0; \delta_2(x,y)\equiv 0} = p + p - \left(\frac{-3}{p}\right) - 1 - \left(\frac{-3}{p}\right) = 2p - 1 - 2\left(\frac{-3}{p}\right).$$
(4.11)

Hence, the second moment times  $p^2$  of the family equals to:

$$p^{2}A_{2,\mathcal{F}}(p) = (p-1)\left[p\left(2p-1-2\left(\frac{-3}{p}\right)\right)+p^{2}(-1)\right]$$
  
=  $p(p-1)\left(p-1-2\left(\frac{-3}{p}\right)\right)$   
=  $p^{3}-2p^{2}+p-2(p^{2}-p)\left(\frac{-3}{p}\right).$  (4.12)

**4.1.3**  $y^2 = x^3 + sx^2 - t^2x$ 

**Lemma 4.5.** The first moment of the two-parameter family  $y^2 = x^3 + sx^2 - t^2x$  is 0.

Proof.

$$\begin{aligned} -p^2 A_{1,\mathcal{F}}(p) &= -\sum_{t(p)} \sum_{s(p)} a_{t,s}(p) = \sum_{t(p)} \sum_{x(p)} \sum_{s(p)} \left( \frac{x^3 + sx^2 - t^2x}{p} \right) \\ &= \sum_{t=1}^{p-1} \sum_{x(p)} \sum_{s(p)} \left( \frac{t^3x^3 + t^2sx^2 - t^3x}{p} \right) \\ &= \sum_{t=1}^{p-1} \sum_{x(p)} \sum_{s(p)} \left( \frac{t^2}{p} \right) \left( \frac{t(x^3 - x) + sx^2}{p} \right) \\ &= \sum_{t=0}^{p-1} \sum_{x(p)} \sum_{s(p)} \left( \frac{t(x^3 - x) + sx^2}{p} \right) - \sum_{x(p)} \sum_{s(p)} \left( \frac{sx^2}{p} \right) \\ &= \sum_{t(p)} \sum_{x(p)} \sum_{s(p)} \left( \frac{t(x^3 - x) + sx^2}{p} \right) - 0 \end{aligned}$$
(4.13)  
$$&= \sum_{t(p)} \sum_{s(p)} \sum_{x=-1,0,1;x(p)} \left( \frac{t(x^3 - x) + sx^2}{p} \right) \\ &+ \sum_{t(p)} \sum_{s(p)} \sum_{x=-1,0,1;x(p)} \left( \frac{t(x^3 - x) + sx^2}{p} \right) \\ &= \sum_{s(p)} \left( \frac{0}{p} \right) + \sum_{s(p)} \left( \frac{-s}{p} \right) + \sum_{s(p)} \left( \frac{s}{p} \right) + \sum_{t(p)} \sum_{s(p)} \sum_{x\neq-1,0,1;x(p)} \left( \frac{t(x^3 - x) + sx^2}{p} \right) - 0 \\ &= 0 \\ &= 0 \end{aligned}$$

**Lemma 4.6.** The second moment of the two-parameter family  $y^2 = x^3 + sx^2 - t^2x$  times  $p^2$  is  $p^3 - p^2$  if  $p \equiv 1 \mod 4$  and  $p^3 - 3p^2 + 2p$  if  $p \equiv 3 \mod 4$ , which supports our Bias Conjecture. Proof.

$$\begin{split} p^{2}A_{2,\mathcal{F}}(p) &= \sum_{t,s(p)} a_{t,s}^{2}(p) \\ &= \sum_{t(p)} \sum_{s(p)} \sum_{x,y(p)} \left( \frac{x^{3} + sx^{2} - t^{2}x}{p} \right) \left( \frac{y^{3} + sy^{2} - t^{2}y}{p} \right) \\ &= \sum_{t=1}^{p-1} \sum_{s(p)} \sum_{x,y(p)} \left( \frac{t^{3}x^{3} + t^{2}sx^{2} - t^{3}x}{p} \right) \left( \frac{t^{3}y^{3} + t^{2}sy^{2} - t^{3}y}{p} \right) \\ &= \sum_{t=1}^{p-1} \sum_{s(p)} \sum_{x,y(p)} \left( \frac{t^{4}}{p} \right) \left( \frac{t(x^{3} - x) + sx^{2}}{p} \right) \left( \frac{t(y^{3} - y) + sy^{2}}{p} \right) \\ &= \sum_{t=0}^{p-1} \sum_{s(p)} \sum_{x,y(p)} \left( \frac{t(x^{3} - x) + sx^{2}}{p} \right) \left( \frac{t(y^{3} - y) + sy^{2}}{p} \right) - \sum_{x,y(p)} \sum_{s(p)} \left( \frac{sx^{2}}{p} \right) \left( \frac{sy^{2}}{p} \right) \end{split}$$

$$= \sum_{x,y(p)} \sum_{s(p)} \sum_{t(p)} \left( \frac{t(x^3 - x) + sx^2}{p} \right) \left( \frac{t(y^3 - y) + sy^2}{p} \right) - (p - 1)^3$$
(4.14)

We compute the discriminant of the equation in terms of t and s:

$$a = (x^{3} - x)(y^{3} - y)$$

$$b = (x^{3} - x)sy^{2} + (y^{3} - y)sx^{2}$$

$$c = s^{2}x^{2}y^{2}$$

$$\delta = b^{2} - 4ac = [(x^{3} - x)sy^{2} - (y^{3} - y)sx^{2}]^{2}$$

$$= [sxy(x - y)(xy + 1)]^{2}.$$
(4.15)

When s is congruent to zero mod p, xy(x-y)(xy+1) does not have to be congruent to zero mod p. For our convenience, we only count the number of times when  $x \neq 0$ , y = 0 and x = 0,  $y \neq 0$ . The contribution is  $(p-1)^2$ .

When s is not congruent to zero mod p, xy(x-y)(xy+1) has to be congruent to zero mod p. The contribution from xy(x-y) is (p-1)(p-1), as  $x \neq 0$ ,  $y \neq 0$  and  $x \neq y$ . Then we have  $xy + 1 \equiv 0(p)$ , so the contribution is also (p-1)(p-1). Hence, its total contribution is (p-1)(p-1)(2p-2).

Therefore, on average  $p^2$  times the second moment equals to

$$pA_{2,\mathcal{F}}(p) = (p-1)^2 + (p-1)(p-1)(2p-2) - (p-1)^3$$
$$= p^3 - 2p^2 + p.$$
(4.16)

When  $x = 7 \neq 0$  and  $p \equiv 1 \mod 4$ , by Dirichlet's theorem for primes in arithmetic progression (Lemma 2.5)  $\left(\frac{x}{p}\right)\left(\frac{-y}{p}\right) = \left(\frac{x^2}{p}\right)$  contributes p. Hence, we have

$$p^{2}A_{2,\mathcal{F}}(p) = p^{3} - 2p^{2} + p + p(p-1)$$
  
=  $p^{3} - p^{2}$ .  
(4.17)

When  $x = y \neq 0$  and  $p \equiv 3 \mod 4$ , by Dirichlet's theorem for primes in arithmetic progression (Lemma 2.5)  $\left(\frac{x}{p}\right)\left(\frac{-y}{p}\right) = -\left(\frac{x^2}{p}\right)$  contributes -p. Hence, we have

$$p^{2}A_{2,\mathcal{F}}(p) = p^{3} - 2p^{2} + p - p(p-1)$$
  
=  $p^{3} - 3p^{2} + 2p.$ 

#### 4.2 Construction of Rank 1 Families

**4.2.1**  $y^2 = x^3 + ts^2x^2 + (t^3 - t^2)x$ 

**Lemma 4.7.** The first moment of the two-parameter family  $y^2 = x^3 + ts^2x^2 + (t^3 - t^2)x$  is -1.

Proof.

$$-p^{2}A_{1,\mathcal{F}}(p) = -\sum_{t(p)}\sum_{s(p)}a_{t,s}(p)$$

$$= \sum_{t(p)}\sum_{x(p)}\sum_{s(p)}\left(\frac{x^{3}+ts^{2}x^{2}+(t^{3}-t^{2})x}{p}\right)$$

$$= \sum_{t(p)}\sum_{s(p)}\sum_{x=1}\left(\frac{t^{3}x^{3}+t^{3}s^{2}x^{2}+t^{4}x-t^{3}x}{p}\right)$$

$$= \sum_{t(p)}\sum_{s(p)}\sum_{x=1}\left(\frac{t^{3}}{p}\right)\left(\frac{x^{3}+s^{2}x^{2}+tx-x}{p}\right)$$

$$= \sum_{x(p)}\sum_{s(p)}\sum_{t(p)}\left(\frac{t}{p}\right)\left(\frac{tx+(x^{3}+s^{2}x^{2}-x)}{p}\right)$$
(4.19)

The t-sum is p-1 if  $p \mid (x^3 + s^2x^2 - x)$  and -1 otherwise. When s is congruent to zero mod  $p, x = \pm 1$  contributes p-1, and other times everything else contributes -1. When s is not congruent to zero mod p, which happens p-1 times, x = 0 contributes p-1 and other times everything else contributes -1. Thus, the total contribution is  $p[2(p-1) + (p-2)(-1)] + (p-1)[1(p-1) + (p-1)(-1)] = p^2$ .

**Lemma 4.8.** The second moment of the two-parameter family  $y^2 = x^3 + ts^2x^2 + (t^3 - t^2)x$ times  $p^2$  is  $p^3 - 3p^2 + 3p - 1$  when  $p \equiv 1 \mod 4$  and  $p^3 - 3p^2 + p + 1$  when  $p \equiv 3 \mod 4$ , which supports our Bias Conjecture. Proof.

$$p^{2}A_{2,\mathcal{F}}(p) = \sum_{t,s(p)} a_{t,s}^{2}(p)$$

$$= \sum_{t(p)} \sum_{s(p)} \sum_{x,y(p)} \left( \frac{x^{3} + ts^{2}x^{2} + (t^{3} - t^{2})x}{p} \right) \left( \frac{y^{3} + ts^{2}y^{2} + (t^{3} - t^{2})y}{p} \right)$$

$$= \sum_{s(p)} \sum_{x,y(p)} \sum_{t=1}^{p-1} \left( \frac{t^{3}x^{3} + t^{3}s^{2}x^{2} + t^{4}x - t^{3}x}{p} \right) \left( \frac{t^{3}y^{3} + t^{3}s^{2}y^{2} + t^{4}y - t^{3}y}{p} \right)$$

$$= \sum_{s(p)} \sum_{x,y(p)} \sum_{t=1}^{p-1} \left( \frac{t^{6}}{p} \right) \left( \frac{tx + x^{3} + s^{2}x^{2} - x}{p} \right) \left( \frac{ty + y^{3} + s^{2}y^{2} - y}{p} \right)$$

$$= \sum_{s(p)} \sum_{x,y(p)} \sum_{t(p)} \left( \frac{tx + x^{3} + s^{2}x^{2} - x}{p} \right) \left( \frac{ty + y^{3} + s^{2}y^{2} - y}{p} \right)$$

$$= \sum_{s(p)} \sum_{x,y(p)} \sum_{t(p)} \left( \frac{x^{3} + s^{2}x^{2} - x}{p} \right) \left( \frac{y^{3} + s^{2}y^{2} - y}{p} \right)$$

$$= \sum_{s(p)} \sum_{x,y(p)} \sum_{t(p)} \left( \frac{tx + x^{3} + s^{2}x^{2} - x}{p} \right) \left( \frac{ty + y^{3} + s^{2}y^{2} - y}{p} \right)$$

$$= \sum_{s(p)} \sum_{x,y(p)} \sum_{t(p)} \left( \frac{tx + x^{3} + s^{2}x^{2} - x}{p} \right) \left( \frac{ty + y^{3} + s^{2}y^{2} - y}{p} \right) - (p^{2} - 1)$$

We compute the discriminant of the equation in terms of t and s:

$$a = xy$$
  

$$b = x(y^{3} + s^{2}y^{2} - y) + y(x^{3} + s^{2}x^{2} - x)$$
  

$$c = (x^{3} + s^{2}x^{2} - x)(y^{3} + s^{2}y^{2} - y)$$
  

$$\delta = b^{2} - 4ac = [x(y^{3} + s^{2}y^{2} - y) - y(x^{3} + s^{2}x^{2} - x)]^{2}$$
  

$$= [xy(y - x)(s^{2} + x + y)]^{2}$$
(4.21)

When x = 0, y can be any number except 0 because we have x = y later (and there's case when x = y = 0. For the same reason, when y = 0, x can be any number except 0. For x = y, there are p values. In all of these three cases, s can be any value except 0 (we have a special case later) so the total contribution is (p-1)[(p-1) + (p-1) + p].

When s is congruent to zero mod p, which happens once,  $x = -y \neq 0$  happens p - 1 times, so its contribution is p - 1.

When s is not congruent to zero mod p, which happens p-1 times, the contribution from  $s^2 + x + y \equiv 0(p)$  is  $(p-1)(p-2)^2$ .

We must be careful about double-counting. When y - x and  $s^2 + x + y$  are both congruent to zero mod p  $(s, x, y \neq 0)$ , we have  $s^2 + 2x \equiv 0(p)$ . Each s has a corresponding x, so the contribution from this case is (p - 1). Hence, on average the second moment times  $p^2$  equals to

$$p^{2}A_{2,\mathcal{F}}(p) = 3(p-1)[(p-1) + (p-1) + p] + (p-1) + (p-1)(p-2)^{2} - (p-1) - (p^{2}-1)$$
$$= p^{3} - 3p^{2} + 2p.$$

If  $p \equiv 1 \mod 4$  and when x = -y, by Dirichlet's theorem for primes in arithmetic progression (Lemma 2.5)  $\left(\frac{x}{p}\right)\left(\frac{-y}{p}\right) = \left(\frac{-1}{p}\right)\left(\frac{x^2}{p}\right) = \left(\frac{x^2}{p}\right)$  contributes an extra p - 1 (as s must equal to 0 and  $x, y \neq 0$ ):

$$p^{2}A_{2,\mathcal{F}(p)} = p^{3} - 3p^{2} + 2p + p - 1$$
  
=  $p^{3} - 3p^{2} + 3p - 1.$  (4.23)

If  $p \equiv 3 \mod 4$  and when x = -y, by Dirichlet's theorem for primes in arithmetic progression (Lemma 2.5)  $\left(\frac{-1}{p}\right)\left(\frac{x^2}{p}\right) = -\left(\frac{x^2}{p}\right)$  contributes an extra -(p-1) (as s must equal to 0 and  $x, y \neq 0$ ):

$$p^{2}A_{2,\mathcal{F}(p)} = p^{3} - 3p^{2} + 2p - (p-1)$$
  
=  $p^{3} - 3p^{2} + p + 1.$  (4.24)

(4.22)

### **4.2.2** $y^2 = x^3 + t^2x^2 + (t^3 - t^2)sx$

**Lemma 4.9.** The first moment of the two-parameter family  $y^2 = x^3 + t^2x^2 + (t^3 - t^2)sx$  is -1.

Proof.

$$p^{2}A_{1,\mathcal{F}}(p) = -\sum_{t(p)} \sum_{s(p)} a_{t,s}(p)$$

$$= \sum_{t(p)} \sum_{x(p)} \sum_{s(p)} \left( \frac{x^{3} + t^{2}x^{2} + (t^{3} - t^{2})sx}{p} \right)$$

$$= \sum_{t(p)} \sum_{s(p)} \sum_{x=1} \left( \frac{t^{3}x^{3} + t^{4}x^{2} + t^{4}sx - t^{3}sx}{p} \right)$$

$$= \sum_{t(p)} \sum_{s(p)} \sum_{x=1} \left( \frac{t^{3}}{p} \right) \left( \frac{x^{3} + tx^{2} + tsx - sx}{p} \right)$$

$$= \sum_{x(p)} \sum_{s(p)} \sum_{t(p)} \sum_{t(p)} \left( \frac{t}{p} \right) \left( \frac{t(x^{2} + sx) + (x^{3} - sx)}{p} \right)$$
(4.25)

The t-sum is p-1 if  $p \mid (x^3 - sx)$  and -1 otherwise. When s is congruent to zero mod p and x = 0, s vanishes so every s contributes p. When s is not congruent to zero mod p, which happens p-1 times,  $x^2 = s \neq 0$  contributes p-1 and other times everything else contributes -1. Thus, the total contribution is  $p^2 + p(p-1)[1(p-1) + (p-1)(-1)] = p^2$ .

**Lemma 4.10.** The second moment of the two-parameter family  $y^2 = x^3 + t^2x^2 + (t^3 - t^2)sx$ times  $p^2$  is  $p^3 - 3p^2 + 3p$  if  $p \equiv 1 \mod 4$  and  $p^3 - 5p^2 + 7p$  if  $p \equiv 3 \mod 4$ , which supports our Bias Conjecture.

Proof.

$$p^{2}A_{2,\mathcal{F}}(p) = \sum_{t,s(p)} a_{t,s}^{2}(p)$$

$$= \sum_{t(p)} \sum_{s(p)} \sum_{x,y(p)} \left( \frac{x^{3} + t^{2}x^{2} + (t^{3} - t^{2})sx}{p} \right) \left( \frac{y^{3} + t^{2}y^{2} + (t^{3} - t^{2})sy}{p} \right)$$

$$= \sum_{s(p)} \sum_{x,y(p)} \sum_{t=1}^{p-1} \left( \frac{t^{3}x^{3} + t^{4}x^{2} + t^{4}sx - t^{3}sx}{p} \right) \left( \frac{t^{3}y^{3} + t^{4}y^{2} + t^{4}sy - t^{3}sy}{p} \right)$$

$$= \sum_{s(p)} \sum_{x,y(p)} \sum_{t=1}^{p-1} \left( \frac{t^{6}}{p} \right) \left( \frac{t(x^{2} + sx) + (x^{3} - sx)}{p} \right) \left( \frac{t(y^{2} + sy) + (y^{3} - sy)}{p} \right)$$

$$= \sum_{s(p)} \sum_{x,y(p)} \sum_{t(p)} \left( \frac{x^{3} - sx}{p} \right) \left( \frac{y^{3} - sy}{p} \right)$$

$$= \sum_{s(p)} \sum_{x,y(p)} \sum_{t(p)} \sum_{t(p)} \left( \frac{t(x^{2} + sx) + (x^{3} - sx)}{p} \right) \left( \frac{t(y^{2} + sy) + (y^{3} - sy)}{p} \right)$$

$$- p(p-1)$$

$$(4.26)$$

The discriminant of the equation equals to

$$a = (x^{2} + sx)(y^{2} + sy)$$

$$b = (x^{2} + sx)(y^{3} - sy) + (y^{2} + sy)(x^{3} - sx)$$

$$c = (x^{3} - sx)(y^{3} - sy)$$

$$\delta = b^{2} - 4ac = [(x^{2} + sx)(y^{3} - sy) - (y^{2} + sy)(x^{3} - sx)]^{2}$$

$$= [xy(x - y)(s(x + y + 1) + xy)]^{2}.$$
(4.27)

We have two special cases when xy is congruent to zero mod p. When x = 0 and y = 1 or y = 0 and x = 1, s vanishes. The contribution from other xy(x - y) cases is  $p(p - 2) + p(p - 2) + p^2 = 3p^2 - 4p$ . Hence, the total contribution is  $3p^2 - 4p + 2$ .

When s is congruent to zero mod p, xy = 0. Since x and y can not equal to zero, there is no contribution from this case. When s is not congruent to zero mod p, the contribution is  $(p-1)^3(x \neq 0 \text{ and } y \neq 0)$ . We must be careful about double-counting. We are aware that if xy and s(x+y+1) + xy are both congruent to zero, we double-count by 2p(p-2) solutions (s can be any value, but  $x \neq 0, 1$  and  $y \neq 0, 1$ ). If x - y and s(x+y+1) + xy are both congruent to zero, we get  $s(2x+1) + x^2 \equiv 0(p)$ . We double-count by (p-1)p + 1 solutions as when  $x \neq 0$ , the contribution is always p except when x = 1, the contribution is 1.

Thus, on average the second moment of this family times  $p^2$  equals to

$$p^{2}A_{2,\mathcal{F}}(p) = 3p^{2} - 4p + 2 + 0 + (p-1)^{3} - 2p(p-2) - (p-1)p - 1 - p(p-1)$$
  
=  $p^{3} - 4p^{2} + 5p.$  (4.28)

If  $p \equiv 1 \mod 4$  and x = -y, by Dirichlet's theorem for primes in arithmetic progression (Lemma 2.5) there is an extra contribution of  $(p-1)^2 + 1$  from  $s - y^2 \equiv 0(p)$ :

$$p^{2}A_{2,\mathcal{F}}(p) = p^{3} - 4p^{2} + 5p + (p-1)^{2} + 1$$
  
=  $p^{3} - 3p^{2} + 3p.$  (4.29)

If  $p \equiv 3 \mod 4$  and x = -y, by Dirichlet's theorem for primes in arithmetic progression (Lemma 2.5) there is an extra contribution of  $-[(p-1)^2 + 1]$  from  $s - y^2 \equiv 0(p)$ :

$$p^{2}A_{2,\mathcal{F}}(p) = p^{3} - 4p^{2} + 5p - [(p-1)^{2} + 1]$$
  
=  $p^{3} - 5p^{2} + 7p.$  (4.30)

#### 4.3 Construction of Rank 2 Families

**4.3.1**  $y^2 = x^3 + t^2 x^2 - (s^2 - s)t^2 x$ 

**Lemma 4.11.** The first moment of the two-parameter family  $y^2 = x^3 + t^2x^2 - (s^2 - s)t^2x$  is -2.

Proof.

$$-p^2 A_{1,\mathcal{F}}(p) = -\sum_{t(p)} \sum_{s(p)} a_{t,s}(p)$$

$$= \sum_{t(p)} \sum_{x(p)} \sum_{s(p)} \left( \frac{x^3 + t^2 x^2 - (s^2 - s)t^2 x}{p} \right)$$
  

$$= \sum_{t(p)} \sum_{s(p)} \sum_{x=1} \left( \frac{t^3 x^3 + t^4 x^2 - (s^2 - s)t^3 x}{p} \right)$$
  

$$= \sum_{t(p)} \sum_{s(p)} \sum_{x=1} \left( \frac{t^3}{p} \right) \left( \frac{x^3 + tx^2 - (s^2 - s)x}{p} \right)$$
  

$$= \sum_{x(p)} \sum_{s(p)} \sum_{t(p)} \left( \frac{t}{p} \right) \left( \frac{tx^2 + (x^3 - (s^2 - s)x)}{p} \right)$$
  
(4.31)

The t-sum is p-1 if  $p \mid (x^3 - (s^2 - s)x)$  and -1 otherwise. When  $s^2 - s$  is congruent to zero mod p - which happens twice - and x = 0, s vanishes so x contributes p. When s is not congruent to zero mod p, every x contributes p-1 ( $x \neq 0$ ). Thus, the total contribution is  $p^2 + p[2(p-1) + (p-2)(-1)] = 2p^2$ .

**Lemma 4.12.** The second moment of the two-parameter family  $y^2 = x^3 + t^2x^2 - (s^2 - s)t^2x$ times  $p^2$  is  $p^3 - 3p^2 + 3p - \sum_{s(p)} \sum_{x,y(p)} \left(\frac{x^3 - (s^2 - s)x}{p}\right) \left(\frac{y^3 - (s^2 - s)y}{p}\right)$  if  $p \equiv 1 \mod 4$  and  $p^3 - 3p^2 + 2p$ if  $p \equiv 3 \mod 4$ , which supports our Bias Conjecture.

Proof.

$$p^{2}A_{2,\mathcal{F}}(p) = \sum_{t,s(p)} a_{t,s}^{2}(p)$$

$$= \sum_{t(p)} \sum_{s(p)} \sum_{x,y(p)} \left( \frac{x^{3} + t^{2}x^{2} - (s^{2} - s)t^{2}x}{p} \right) \left( \frac{y^{3} + t^{2}y^{2} - (s^{2} - s)t^{2}y}{p} \right)$$

$$= \sum_{s(p)} \sum_{x,y(p)} \sum_{t=1}^{p-1} \left( \frac{t^{3}x^{3} + t^{4}x^{2} - (s^{2} - s)t^{3}x}{p} \right) \left( \frac{t^{3}y^{3} + t^{4}y^{2} - (s^{2} - s)t^{3}y}{p} \right)$$

$$= \sum_{s(p)} \sum_{x,y(p)} \sum_{t=1}^{p-1} \left( \frac{t^{6}}{p} \right) \left( \frac{tx^{2} + (x^{3} - (s^{2} - s)x)}{p} \right) \left( \frac{ty^{2} + (y^{3} - (s^{2} - s)y)}{p} \right)$$

$$= \sum_{s(p)} \sum_{x,y(p)} \left( \frac{x^{3} - (s^{2} - s)x}{p} \right) \left( \frac{y^{3} - (s^{2} - s)y}{p} \right)$$

$$= \sum_{s(p)} \sum_{x,y(p)} \sum_{t(p)} \left( \frac{tx^{2} + (x^{3} - (s^{2} - s)x)}{p} \right) \left( \frac{ty^{2} + (y^{3} - (s^{2} - s)y)}{p} \right) -$$

$$- \sum_{s(p)} \sum_{x,y(p)} \left( \frac{x^{3} - (s^{2} - s)x}{p} \right) \left( \frac{y^{3} - (s^{2} - s)y}{p} \right)$$

We compute the discriminant of the equation in terms of t and s:

$$a = x^2 y^2$$
  

$$b = (y^3 - (s^2 - s)y)x^2 + (x^3 - (s^2 - s)x)y^2$$

$$c = (y^{3} - (s^{2} - s)y)(x^{3} - (s^{2} - s)x)$$
  

$$\delta = b^{2} - 4ac = [(y^{3} - (s^{2} - s)y)x^{2} - (x^{3} - (s^{2} - s)x)y^{2}]^{2}$$
  

$$= [xy(x - y)(-s^{2} + s - xy)]^{2}$$
(4.33)

The contribution from xy(x-y) is  $p(p-1) + p(p-1) + p^2 = 3p^2 - 2p$ .

When s = 0 or s = -1,  $-s^2 + s$  is congruent to zero mod p. We need  $xy \equiv 0(p)$ . However, there is no contribution, since  $x \neq 0$  and  $y \neq 0$ .

When  $-s^2 + s$  is not congruent to zero mod p, we need  $-s^2 + s - xy \equiv 0(p)$ . The contribution from this case is  $(p-2)(p-1)^2$ .

Last but not least, we calculate the double-counting cases. When xy and  $-s^2 + s - xy$  are both congruent to zero mod p, the contribution is 2. When x - y and  $-s^2 + s - xy$  are both congruent to zero mod p, we have  $-s^2 + s - x^2 \equiv 0(p)$  and the contribution is  $2p^2 - 2$  ( $s \neq 0, 1$ ).

Thus, on average the second moment of this family times  $p^2$  equals to:

$$p^{2}A_{2,\mathcal{F}}(p) = 3p^{2} - 2p + 0 + (p-2)(p-1)^{2} - (2p^{2} - 2)$$
  
$$-\sum_{s(p)} \sum_{x,y(p)} \left(\frac{x^{3} - (s^{2} - s)x}{p}\right) \left(\frac{y^{3} - (s^{2} - s)y}{p}\right)$$
  
$$= p^{3} - 3p^{2} + 3p - \sum_{s(p)} \sum_{x,y(p)} \left(\frac{x^{3} - (s^{2} - s)x}{p}\right) \left(\frac{y^{3} - (s^{2} - s)y}{p}\right).$$
(4.34)

Keep in mind that although we have an extra term in the second moment above, the term will contribute positive values, making the negative bias larger. Hence, the Bias Conjecture still holds.

If  $p \equiv 1 \mod 4$ , there is an extra contribution of p as s can be any value:

$$p^{2}A_{2,\mathcal{F}}(p) = p^{3} - 3p^{2} + 3p - \sum_{s(p)} \sum_{x,y(p)} \left(\frac{x^{3} - (s^{2} - s)x}{p}\right) \left(\frac{y^{3} - (s^{2} - s)y}{p}\right) + p$$
  
$$= p^{3} - 3p^{2} + 4p - \sum_{s(p)} \sum_{x,y(p)} \left(\frac{x^{3} - (s^{2} - s)x}{p}\right) \left(\frac{y^{3} - (s^{2} - s)y}{p}\right).$$

$$(4.35)$$

If  $p \equiv 3 \mod 4$ ,  $\sum_{s(p)} \sum_{x(p)} \left(\frac{x^3 - (s^2 - s)x}{p}\right) = \sum_{s(p)} \sum_{x(p)} \left(\frac{x}{p}\right) \left(\frac{x^2 - s^2 + s}{p}\right) = 0$  because the two distinct solutions to  $1 + 4x^2 \equiv 0 \mod p$  are both non-squares modulo p. In addition, there is an extra contribution of -p as s can be any value:

$$p^{2}A_{2,\mathcal{F}}(p) = p^{3} - 3p^{2} + 3p - 0 - p$$
  
=  $p^{3} - 3p^{2} + 2p.$ 

(4.36)

**4.3.2**  $y^2 = x^3 - t^2x + t^3s^2 + t^4$ 

**Lemma 4.13.** The first moment of the two-parameter family  $y^2 = x^3 - t^2x + t^3s^2 + t^4$  is -2. Proof.

$$-p^{2}A_{1,\mathcal{F}}(p) = -\sum_{t(p)}\sum_{s(p)}a_{t,s}(p)$$

$$= \sum_{t(p)}\sum_{x(p)}\sum_{s(p)}\left(\frac{x^{3}-t^{2}x+t^{3}s^{2}+t^{4}}{p}\right)$$

$$= \sum_{t(p)}\sum_{s(p)}\sum_{x=1}\left(\frac{t^{3}x^{3}-t^{3}x+t^{3}s^{2}+t^{4}}{p}\right)$$

$$= \sum_{t(p)}\sum_{s(p)}\sum_{x=1}\left(\frac{t^{3}}{p}\right)\left(\frac{x^{3}-x+s^{2}+t}{p}\right)$$

$$= \sum_{x(p)}\sum_{s(p)}\sum_{t(p)}\left(\frac{t}{p}\right)\left(\frac{t+(x^{3}-x+s^{2})}{p}\right)$$
(4.37)

The t-sum is p-1 if  $p \mid x^3 - x + s^2$  and -1 otherwise. When  $s^2 = 0$ , each of x = -1, 0, 1 contributes p-1 and everything else contributes -1. When  $s^2 \neq 0$ , one x value contributes p-1 and everything else contributes -1. Thus, the total contribution is  $p[3(p-1) + (p-3)(-1)] + (p-1)[1(p-1) + (p-1)(-1)] = 2p^2$ .

**Lemma 4.14.** The second moment of the two-parameter family  $y^2 = x^3 - t^2x + t^3s^2 + t^4$  times  $p^2$  is  $p^3 - 2p^2 + p - \left[\left(\frac{-3}{p}\right) + \left(\frac{3}{p}\right)\right]p^2$ , which supports our Bias Conjecture.

Proof.

$$p^{2}A_{2,\mathcal{F}}(p) = \sum_{t,s(p)} a_{t,s}^{2}(p)$$

$$= \sum_{t(p)} \sum_{s(p)} \sum_{x,y(p)} \left(\frac{x^{3} - t^{2}x + t^{3}s^{2} + t^{4}}{p}\right) \left(\frac{y^{3} - t^{2}y + t^{3}s^{2} + t^{4}}{p}\right)$$

$$= \sum_{s(p)} \sum_{x,y(p)} \sum_{t=1}^{p-1} \left(\frac{t^{3}x^{3} - t^{3}x + t^{3}s^{2} + t^{4}}{p}\right) \left(\frac{t^{3}y^{3} - t^{3}y + t^{3}s^{2} + t^{4}}{p}\right)$$

$$= \sum_{s(p)} \sum_{x,y(p)} \sum_{t=1}^{p-1} \left(\frac{t^{6}}{p}\right) \left(\frac{t + (x^{3} - x + s^{2})}{p}\right) \left(\frac{t + (y^{3} - y + s^{2})}{p}\right)$$

$$= \sum_{s(p)} \sum_{x,y(p)} \sum_{t(p)} \left(\frac{x^{3} - x + s^{2}}{p}\right) \left(\frac{y^{3} - y + s^{2}}{p}\right)$$

$$= \sum_{s(p)} \sum_{x,y(p)} \sum_{t(p)} \left(\frac{t + (x^{3} - x + s^{2})}{p}\right) \left(\frac{t + (y^{3} - y + s^{2})}{p}\right) - p(p-1)$$
(4.38)

We compute the discriminant of the equation in terms of t and s:

$$a = 1$$
  

$$b = (x^{3} - x + s^{2}) + (y^{3} - y + s^{2})$$
  

$$c = (x^{3} - x + s^{2})(y^{3} - y + s^{2})$$
  

$$\delta = b^{2} - 4ac = [(x^{3} - x + s^{2}) - (y^{3} - y + s^{2})]^{2}$$
  

$$= [(x - y)(x^{2} + xy + y^{2} - 1)]^{2}$$
(4.39)

We see that s disappears, so every s has the same contribution. The solutions to the first factor are x = y, which happens p times. For fixed x, the discriminant of the second factor can be rewritten as  $\frac{-x\pm\sqrt{4-3x^2}}{2}$ , and the sum is  $\sum_{x=1}^{p-1} \left[1 + \left(\frac{4-3x^2}{p}\right)\right] = p - 1 - \left(\frac{-3}{p}\right)$ . We must be careful about double-counting. When both factors are congruent to zero mod p, some pairs satisify  $3x^2 \equiv 1$ . If  $\binom{3}{p} = 1$  we have double-counted two solutions; if it is -1, there was no double counting. Hence, the contribution is  $p^2(p-1-\left[\left(\frac{-3}{p}\right)+\left(\frac{3}{p}\right)\right]$ .

Thus,

$$p^{2}A_{2,\mathcal{F}}(p) = p^{2}(p-1) - \left[\left(\frac{-3}{p}\right) + \left(\frac{3}{p}\right)\right] - p(p-1)$$
  
$$= p^{3} - 2p^{2} + p - \left[\left(\frac{-3}{p}\right) + \left(\frac{3}{p}\right)\right]p^{2}.$$
(4.40)

#### 5 Conclusion and Future Work

We have shown in every one- and two-parameter family we are able to prove theoretically the largest lower order term that does not average to zero has a negative average. For the families we are unable to prove theoretically, we conjecture that these terms of their second moments on average are negative from the data we get. However, because of our limitation to generate data, we are not sure if the form contains terms of size  $p^{3/2}$  because they dwarf the smaller order p terms and make them hard to see. We can investigate on finding a more efficient way to generate data. In particular, there are families with terms of size  $p^{3/2}$  that average to zero, and are followed by terms of size p with a negative average.

While we have concentrated on the second moments of the Fourier coefficients in elliptic curves, there are a lot of other fields we can explore. For example, we can explore higher ranks (> 2), higher moments (> 2) as well as other families, and see if similar biases exist. The difficulty is that the resulting sums can not be handled by existing techniques; in general we can not even compute a(p) for a given elliptic curve, as we can not do cubic Legendre sums.

Another area we want to focus on in the future is getting to know the two-parameter families better. What are the implications of the negative bias of the two-parameter families? How do they behave differently from one-parameter families or other families and why?

We have two tables below: the first table records the rank, the first moment times p and the second moment times p of every one-parameter family we prove theoretically or generate data for the first 100 primes in this paper; the second table records the rank, the first moment times  $p^2$  and the second moment times  $p^2$  of every two-parameter family we prove theoretically. We set  $\delta_1(p)$  to be 1 if  $p \equiv 1 \mod 4$  and 0 otherwise, and  $\delta_3(p)$  to be 1 if  $p \equiv 3 \mod 4$  and 0 otherwise.

One-Parameter Family	Rank	$pA_{1,\mathcal{F}(p)}$	$pA_{2,\mathcal{F}(p)}$
$y^2 = x^3 - x^2 - x + t$	0	0	$p^2 - 2p - \left(\frac{-3}{p}\right)p$
$y^2 = x^3 - tx^2 + (x - 1)t^2$	0	0	$p^2 - 2p - \left[\sum_{x(p)} \left(\frac{x^3 - x^2 + x}{p}\right)\right]^2 - \left(\frac{-3}{p}\right)p$
$y^2 = x^3 + tx^2 + t^2$	1	-р	$p^2 - 2p - \left(\frac{-3}{p}\right)p - 1$
$y^2 = x^3 + tx^2 + x + 1$	1	-р	$p^2 - p - 1 + p \sum_{x(p)} \left(\frac{4x^3 + x^2 + 2x + 1}{p}\right)$
$y^2 = x^3 + tx^2 + tx + t^2$	1	-р	$p^2 - p - 1 - \delta_1(p)(2p)$
$y^2 = x^3 - x^2 + (x^2 - x)t + 1$	2	-2p	$p^2 - 1$ ("conjectured on average")
$y^2 = x^3 - x + t^4$	2("conjectured on average")	-2p ("conjectured on average")	$p^2 - p$ ("conjectured on average")

Table 3: The one-parameter families we proved theoretically all show that the largest lower order term that does not average to zero has a negative average. Unfortunately, we are not able to prove the second moment of  $y^2 = x^3 - x^2 + (x^2 - x)t + 1$  as well as the first and second moment of  $y^2 = x^3 - x + t^4$  theoretically. We only generated data for the first 100 primes to get a sense of the behavior as no finite computation will be a proof. Also, keep in mind that we did not observe the same form for every prime; we conjectured the average of its first or second moment. One family worth noting is  $y^2 = x^3 - x^2 + (x^2 - x)t + 1$ ; it is a potential counterexample to a stronger form of Miller's Bias Conjecture based on the families studied to date, which is that in the second moment expansion the first term that does not average to zero is the *p* term and that has a negative average.

Two-Parameter Family	$p^2 A_{1,\mathcal{F}(p)}$	$p^2 A_{2,\mathcal{F}(p)}$
$y^2 = x^3 + tx + sx^2$	0	$p^3 - 2p^2 + p$
$y^2 = x^3 + t^2x + st^4$	0	$p^3 - 2p^2 + p - 2(p^2 - p)\left(\frac{-3}{p}\right)$
$y^2 = x^3 + sx^2 - t^2x$	0	$p^3 - p^2 - \delta_3(p)(2p^2 - 2p)$
$y^{2} = x^{3} + ts^{2}x^{2} + (t^{3} - t^{2})x$	$-p^2$	$p^3 - 3p^2 + 3p - 1 - \delta_3(p)(2p - 2)$
$y^2 = x^3 + t^2x^2 + (t^3 - t^2)sx$	$-p^{2}$	$p^3 - 3p^2 + 3p - \delta_3(p)(2p^2 - 4p)$
$y^{2} = x^{3} + t^{2}x^{2} - (s^{2} - s)t^{2}x$	$-2p^{2}$	$p^{3} - 3p^{2} + 2p + \delta_{1}(p)\left(p - \sum_{s(p)}\sum_{x,y(p)} \left(\frac{x^{3} - (s^{2} - s)x}{p}\right)\left(\frac{y^{3} - (s^{2} - s)y}{p}\right)\right)$
$y^2 = x^3 - t^2x + t^3s^2 + t^4$	$-2p^2$	$p^3 - 2p^2 + p - \left[\left(\frac{-3}{p}\right) + \left(\frac{3}{p}\right)\right]p^2$

Table 4: The two-parameter families we proved theoretically all show a negative bias in the largest lower order term in the second-moment expansion.

#### 6 Acknowledgements

First of all, I want to thank my mentor, Professor S. J. Miller, for his patience and dedication throughout the research process. Elliptic Curve is an intricate and exciting topic; without his guidance, I would not be able to familiarize with it quickly and explore its new realms.

I am also deeply grateful to my family, friends, and teachers for their unwavering support. They are willing to listen to my doubts, frustrations, and happiness and help me balance this project with other aspects of my life.

Pursuing this project has made me realized the fun behind the amount of work that is being put into research as a mathematician. I hope that one day, I will be able to spread the beauty of mathematics and help others.

#### 7 Declaration of Academic Integrity

I solemnly declare that the paper I submitted is under the guidance of my mentor. As far as I am concerned, except the citations and references listed, this paper does not contain others' works. If not true, I will assume all responsibilities.

### A Proof of Linear and Quadratic Legendre Sums

Lemma A.1 (Linear Legendre Sum).

$$\sum_{x \mod p} \left(\frac{ax+b}{p}\right) = 0 \ if \ p \nmid a.$$
(A.1)

*Proof.* Since  $p \nmid a$ , there are exactly  $\frac{p-1}{2}$  quadratic residues,  $\frac{p-1}{2}$  quadratic nonresidues, and 1 number that is divisible by p in a system of residues modulo p. Hence, linear legendre sum equals to

$$\sum_{x \mod p} \left(\frac{ax+b}{p}\right) = \left(\frac{p-1}{2}\right) \times 1 + \frac{p-1}{2} \times -1 + 1 \times 0 = 0.$$
(A.2)

**Lemma A.2** (Quadratic Legendre Sum). Let a, b, c be positive integers. Assume p > 2 and  $a \neq 0 \mod p$ , we have:

$$\sum_{x \bmod p} \left( \frac{ax^2 + bx + c}{p} \right) = \begin{cases} -\left(\frac{a}{p}\right), & \text{if } p \nmid b^2 - 4ac. \\ (p-1)\left(\frac{a}{p}\right), & \text{if } p \mid b^2 - 4ac. \end{cases}$$
(A.3)

Proof.

$$\sum_{x \mod p} \left( \frac{ax^2 + bx + c}{p} \right) = \left( \frac{a^{-1}}{p} \right) \sum_{x \mod p} \left( \frac{a^2x^2 + bax + ac}{p} \right)$$

$$= \left( \frac{a}{p} \right) \sum_{x \mod p} \left( \frac{x^2 + bx + ac}{p} \right)$$

$$= \left( \frac{a}{p} \right) \sum_{x \mod p} \left( \frac{x^2 + bx + 4^{-1}b^2 + ac - 4^{-1}b^2}{p} \right)$$

$$= \left( \frac{a}{p} \right) \sum_{x \mod p} \left( \frac{(x + 2^{-1}b)^2 - 4^{-1}(b^2 - 4ac)}{p} \right)$$

$$= \sum_{x \mod p} \left( \frac{a}{p} \right) \left( \frac{x^2 - D}{p} \right)$$
(A.4)

We have three cases in total:

Case 1: If D is zero mod p, then the sum equals to:

$$\sum_{x=0}^{p-1} \left(\frac{x^2}{p}\right) = p - 1.$$

(A.5)

Case 2: If D is a non-zero square mod p, then

$$\sum_{x=0}^{p-1} \left(\frac{x^2 - D}{p}\right) = \sum_{x=0}^{p-1} \left(\frac{x+d}{p}\right) \left(\frac{x-d}{p}\right) = -1.$$
(A.6)

where  $d^2 = D$ . Shift x by d, and then replace x with (2d)x, we have:

$$S(d) = \sum_{x=0}^{p-1} \left(\frac{x+2d}{p}\right) \left(\frac{x}{p}\right)$$
$$= \sum_{x=0}^{p-1} \left(\frac{2dx+2d}{p}\right) \left(\frac{2dx}{p}\right)$$
$$= \left(\frac{2d}{p}\right)^2 \sum_{x=0}^{p-1} \left(\frac{x+1}{p}\right) \left(\frac{x}{p}\right)$$
$$= S(1).$$
(A.7)

Note that  $\sum_{d=0}^{p-1} S(d)$  equals to 0, so  $\sum_{d \mod p} S(d)$  equals to 0. We can also see that if d is not 0, then S(d) = S(1) because  $\left(\frac{2d}{p}\right)^2$  equals to 1, and if we move 2d by 1, the two equations are equivalent to each other. If d equals to 0, S(0) = p - 1 because  $\left(\frac{x+d}{p}\right)\left(\frac{x}{p}\right)$  now becomes  $\left(\frac{x}{p}\right)^2$ . Hence,

$$\sum_{d \mod p} S(d) = S(0) + \sum_{d=1}^{p-1} S(1)$$
  
=  $(p-1) + (p-1)S(1).$  (A.8)

Thus, S(1) = -1.

Case 3: When D is not a square, we use the multiplicative property of Legendre sums (i.e when p is a prime, (0, 1, 2, ..., p-1) is the same as  $(1, g, g^2, ..., g^{p-1})$  for some generator g) to compute the sum. We can rewrite D as  $g^{2k+1}$  because anything of the form  $g^{2k}$  is a perfect square mod p, and of the form  $g^{2k+1}$  is not. We can also rewrite x as  $g^k x$  because summing over  $x \mod p$  is the same as summing over  $g^k x \mod p$ . Therefore, we have

$$\sum_{x \mod p} \left(\frac{g^{2k}x^2 - g^{2k+1}}{p}\right) = \sum_{x \mod p} \left(\frac{g^{2k}}{p}\right) \left(\frac{x^2 - g}{p}\right) = \sum_{x \mod p} \left(\frac{x^2 - g}{p}\right).$$
(A.9)

Thus,  $S(g^{2k+1}) = S(g)$  for all k, which means contribution for  $\left(\frac{x^2-g}{p}\right)$  is the same.

Define the set of non-zero squares as S and the set of non-squares as N. This shows that for all non-squares, the contribution is the same and it is the sum of  $\left(\frac{x^2-g}{p}\right)$ . Since

 $\sum_{D=0}^{p-1} \sum_{x=0}^{p-1} \left(\frac{x^2 - D}{p}\right) = 0$ , the quadratic Legendre sum S(g) when D is not a square equals to:

$$\sum_{D=0}^{p-1} \sum_{x=0}^{p-1} \left( \frac{x^2 - D}{p} \right) = \sum_{x=0}^{p-1} \left( \frac{x^2}{p} \right) + \sum_{D \in \mathcal{S}} \sum_{x=0}^{p-1} \left( \frac{x^2 - D}{p} \right) + \sum_{g \in \mathcal{N}} \sum_{x=0}^{p-1} \left( \frac{x^2 - g}{p} \right)$$
$$= (p-1) + \frac{p-1}{2} (-1) + \frac{p-1}{2} S(g).$$
(A.10)

Hence, S(g) = -1.

#### **B** Proof of Rational Surfaces for One-Parameter Families

In this section, we will prove that the one-parameter families we computed are rational surfaces using Tate's Conjecture for Elliptic Surfaces (Conjecture 2.2), or else the first moment does not equal to their rank.

#### **B.1** Rank 0 One-Parameter Families

**B.1.1**  $y^2 = x^3 - x^2 - x - t$ 

**Lemma B.1.** One-parameter family  $y^2 = x^3 - x^2 - x - t$  is a rational surface.

Proof. We first convert the family to its Weierstrass form and we have

$$a'2 = -1,$$
  

$$a'4 = -1,$$
  

$$a'6 = -t,$$
  

$$a''4 = -1 - \frac{1}{3}(-1)^2 = -\frac{4}{3},$$
  

$$a''6 = -t + \frac{2}{27}(-1)^3 - \frac{1}{3} \cdot (-1) \cdot (-1) = -t - \frac{11}{27}.$$
  
(B.1)

Hence, we get

$$y^2 = x^3 - \frac{4}{3}x - t - \frac{11}{27}.$$
 (B.2)

Recall that Tate's conjecture is known for rational surfaces: an elliptic curve  $y^2 = x^3 + A(T)x + B(T)$  is rational if  $0 < \max(3 \deg A, 2 \deg B) < 12$  is true. In this family,  $0 < \max(3 \deg A = 0, 2 \deg B = 2) = 2 < 12$ , so the family is a rational surface.

**B.1.2**  $y^2 = x^3 - tx^2 + (x - 1)t^2$ 

**Lemma B.2.** One-parameter family  $y^2 = x^3 - tx^2 + (x - 1)t^2$  is a rational surface.

Proof. We first convert the family to its Weierstrass form and we have

$$a'2 = -t,$$
  

$$a'4 = t^{2},$$
  

$$a'6 = -t^{2},$$
  

$$a''4 = t^{2} - \frac{1}{3}(-t)^{2} = \frac{2}{3}t^{2},$$
  

$$a''6 = -t^{2} + \frac{2}{27}(-t)^{3} - \frac{1}{3} \cdot (-t) \cdot (t^{2}) = -t^{2} + \frac{7}{27}t^{3}.$$
  
(B.3)

Hence, we get

$$y^{2} = x^{3} + \frac{2}{3}t^{2}x - t^{2} + \frac{7}{27}t^{3}.$$
 (B.4)

Recall that Tate's conjecture is known for rational surfaces: an elliptic curve  $y^2 = x^3 + A(T)x + B(T)$  is rational if  $0 < \max(3 \deg A, 2 \deg B) < 12$  is true. In this family,  $0 < \max(3 \deg A) = 6, 2 \deg B = 6 = 6 < 12$ , so this family is a rational surface.

#### **B.2** Rank 1 One-Parameter Families

**B.2.1** 
$$y^2 = x^3 + tx^2 + t^2$$

**Lemma B.3.** One-parameter family  $y^2 = x^3 + tx^2 + t^2$  is a rational surface.

*Proof.* We first convert the family to its Weierstrass form and we have

$$\begin{aligned} a'2 &= t, \\ a'4 &= 0, \\ a'6 &= t^2, \\ a''4 &= 0 - \frac{1}{3}t^2 = -\frac{1}{3}t^2, \\ a''6 &= t^2 + \frac{2}{27}t^3 - \frac{1}{3} \cdot 0 \cdot t = t^2 + \frac{2}{27}t^3. \end{aligned}$$
(B.5)

Hence, we get

$$y^{2} = x^{3} - \frac{1}{3}t^{2}x + t^{2} + \frac{2}{27}t^{3}.$$
 (B.6)

Recall that Tate's conjecture is known for rational surfaces: an elliptic curve  $y^2 = x^3 + A(T)x + B(T)$  is rational if  $0 < \max(3 \deg A, 2 \deg B) < 12$  is true. In this family,  $0 < \max(3 \deg A) = 6, 2 \deg B = 6 = 6 < 12$ , so this family is a rational surface.

**B.2.2** 
$$y^2 = x^3 + tx^2 + x + 1$$

**Lemma B.4.** One-parameter family  $y^2 = x^3 + tx^2 + x + 1$  is a rational surface.

Proof. We first convert the family to its Weierstrass form and we have

$$a'2 = t$$
  

$$a'4 = 1$$
  

$$a'6 = 1$$
  

$$a''4 = 1 - \frac{1}{3}t^{2}$$
  

$$a''6 = 1 + \frac{2}{27}t^{3} - \frac{1}{3} \cdot 1 \cdot t = 1 + \frac{2}{27}t^{3} - \frac{1}{3}t.$$
  
(B.7)

Hence, we get

$$y^{2} = x^{3} + (1 - \frac{1}{3}t^{2})x + 1 + \frac{2}{27}t^{3} - \frac{1}{3}t.$$
 (B.8)

In this family,  $0 < \max(3 \deg A = 6, 2 \deg B = 6) = 6 < 12$ , so this family is a rational surface.

**B.2.3**  $y^2 = x^3 + tx^2 + tx + t^2$ 

**Lemma B.5.** One-parameter family  $y^2 = x^3 + tx^2 + tx + t^2$  is a rational surface.

*Proof.* We first convert the family to its Weierstrass form using and we have:

$$a'2 = t$$

$$a'4 = t$$

$$a'6 = t^{2}$$

$$a''4 = t - \frac{1}{3}t^{2} = \frac{2}{3}t^{2}$$

$$a''6 = t^{4} + \frac{2}{27}t^{3} - \frac{1}{3} \cdot t \cdot t = t^{4} + \frac{2}{27}t^{3} - \frac{1}{3}t^{2}.$$
(B.9)

Hence, we get

$$y^{2} = x^{3} + \frac{2}{3}t^{2}x + t^{4} + \frac{2}{27}t^{3} - \frac{1}{3}t^{2}.$$
 (B.10)

In this family,  $0 < \max(3 \deg A = 6, 2 \deg B = 8) = 8 < 12$ , so this family is a rational surface.

#### B.3 Rank 2 One-Parameter Families

**B.3.1**  $y^2 = x^3 - x^2 + (x^2 - x)t + 1$ 

**Lemma B.6.** One-parameter family  $y^2 = x^3 - x^2 + (x^2 - x)t + 1$  is a rational surface.

*Proof.* We first convert the family to its Weierstrass form and we have:

$$a'2 = t-1$$

$$a'4 = -t$$

$$a'6 = 1$$

$$a''4 = -t - \frac{1}{3}(-1)^2 = -t - \frac{1}{3}$$

$$a''6 = 1 + \frac{2}{27}(t-1)^3 - \frac{1}{3} \cdot (t-1) \cdot (-t) = 1 + \frac{2}{27}(t-1)^3 + \frac{1}{3}(t^2 - t).$$
(B.11)

Hence, we get

$$y^{2} = x^{3} - \left(-t - \frac{1}{3}\right)x + t^{2} + 1 + \frac{2}{27}(t - 1)^{3} + \frac{1}{3}(t^{2} - t).$$
(B.12)

In this family,  $0 < \max(3 \deg A = 3, 2 \deg B = 6) = 6 < 12$ , so the family is a rational surface.

**B.3.2** 
$$y^2 = x^3 - x + t^4$$

**Lemma B.7.** One-parameter family  $y^2 = x^3 - x + t^4$  is a rational surface.

*Proof.* This family is already in its Weierstrass form. In this family,  $0 < \max(3 \deg A = 0, 2 \deg B = 8) = 8 < 12$ , so this family is a rational surface.

### C Data Table For Rank 2 One-Parameter Families

р	$pA_{2,\mathcal{F}(p)}$	Form

# C.3 Second Moment of $x^3 - x + t^4$

# D Mathematica Code For Computing the First and Second Moment

#### D.1 First Moment Computation

p = 13; Sum[Sum[JacobiSymbol[(x<sup>3</sup>-x+t<sup>4</sup>), p],{x, 0, p-1}],{t,0,p-1}]

#### D.2 Second Moment Computation

```
h[u_, v_] := v^3 - v^2 + (v^2 - v) u + 1;
f[p_] := Sum[
Sum[Sum[JacobiSymbol[h[t, x] h[t, y], p], {x, 0, p - 1}], {y, 0,
    p - 1}], {t, 0, p - 1}];
g[p_] := 1.0 (f[p] - p^2)/p;
secondmomentrange[nstart_, nend_] :=
Module[{}, For[n = nstart, n <= nend, n++, {prime = Prime[n];
Print["We are looking at the prime ", prime];
Print["The second moment term Sum_{t,x,y mod p} a_t(p)^2 is ",
    f[prime]];
Print["The second moment minus p^2 then divided by p is ",
    g[prime]];
Print[" "]'}];];
```

D.3 Statistics Display

data = {}
