http://web.williams.edu/Mathematics/sjmiller/public_html/

Québec-Vermont Number Theory Seminar
Concordia University, March 21, 2013
Introduction
Why study zeros of $L$-functions?

- Infinitude of primes, primes in arithmetic progression.
- Chebyshev’s bias: $\pi_{3,4}(x) \geq \pi_{1,4}(x)$ ‘most’ of the time.
- Birch and Swinnerton-Dyer conjecture.
- Goldfeld, Gross-Zagier: bound for $h(D)$ from $L$-functions with many central point zeros.
- Even better estimates for $h(D)$ if a positive percentage of zeros of $\zeta(s)$ are at most $1/2 - \epsilon$ of the average spacing to the next zero.
Distribution of zeros

- $\zeta(s), L(s, \chi) \neq 0$ for $\Re(s) = 1$: $\pi(x), \pi_{a,q}(x)$.

- **GRH**: error terms.

- **GSH**: Chebyshev’s bias.

- Analytic rank, adjacent spacings: $h(D)$. 
Goals

- Determine correct scale and statistics to study zeros of $L$-functions.

- See similar behavior in different systems (random matrix theory).

- Discuss the tools and techniques needed to prove the results.

- State new GL(2) results, sketch proofs in simple families.
Fundamental Problem: Spacing Between Events

**General Formulation:** Studying system, observe values at $t_1, t_2, t_3, \ldots$.

**Question:** What rules govern the spacings between the $t_i$?

**Examples:**

- Spacings b/w Energy Levels of Nuclei.
- Spacings b/w Eigenvalues of Matrices.
- Spacings b/w Primes.
- Spacings b/w $n^k \alpha \mod 1$.
- Spacings b/w Zeros of $L$-functions.
In studying many statistics, often three key steps:

1. Determine correct scale for events.

2. Develop an explicit formula relating what we want to study to something we understand.

3. Use an averaging formula to analyze the quantities above.

It is not always trivial to figure out what is the correct statistic to study!
Classical Random Matrix Theory
Origins of Random Matrix Theory

Classical Mechanics: 3 Body Problem Intractable.

Heavy nuclei (Uranium: 200+ protons / neutrons) worse!

Get some info by shooting high-energy neutrons into nucleus, see what comes out.

Fundamental Equation:

\[ H \psi_n = E_n \psi_n \]

- \( H \): matrix, entries depend on system
- \( E_n \): energy levels
- \( \psi_n \): energy eigenfunctions
Origins of Random Matrix Theory

- Statistical Mechanics: for each configuration, calculate quantity (say pressure).
- Average over all configurations – most configurations close to system average.
- Nuclear physics: choose matrix at random, calculate eigenvalues, average over matrices (real Symmetric $A = A^T$, complex Hermitian $\bar{A}^T = A$).
Classical Random Matrix Ensembles

\[
A = \begin{pmatrix}
a_{11} & a_{12} & a_{13} & \cdots & a_{1N} \\
a_{12} & a_{22} & a_{23} & \cdots & a_{2N} \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
a_{1N} & a_{2N} & a_{3N} & \cdots & a_{NN}
\end{pmatrix} = A^T, \quad a_{ij} = a_{ji}
\]

Fix \( p \), define

\[
\text{Prob}(A) = \prod_{1 \leq i \leq j \leq N} p(a_{ij}).
\]

This means

\[
\text{Prob} \left( A : a_{ij} \in [\alpha_{ij}, \beta_{ij}] \right) = \prod_{1 \leq i \leq j \leq N} \int_{x_{ij} = \alpha_{ij}}^{\beta_{ij}} p(x_{ij}) \, dx_{ij}.
\]

Want to understand eigenvalues of \( A \).
Eigenvalue Distribution

\( \delta(x - x_0) \) is a unit point mass at \( x_0 \):

\[
\int f(x) \delta(x - x_0) \, dx = f(x_0).
\]
Eigenvalue Distribution

\[ \delta(x - x_0) \text{ is a unit point mass at } x_0: \]
\[ \int f(x)\delta(x - x_0)\,dx = f(x_0). \]

To each \( A \), attach a probability measure:

\[ \mu_{A,N}(x) = \frac{1}{N} \sum_{i=1}^{N} \delta \left( x - \frac{\lambda_i(A)}{2\sqrt{N}} \right) \]
Eigenvalue Distribution

\[ \delta(x - x_0) \text{ is a unit point mass at } x_0: \]
\[ \int f(x)\delta(x - x_0)\,dx = f(x_0). \]

To each \( A \), attach a probability measure:

\[ \mu_{A,N}(x) = \frac{1}{N} \sum_{i=1}^{N} \delta \left( x - \frac{\lambda_i(A)}{2\sqrt{N}} \right) \]

\[ \int_{a}^{b} \mu_{A,N}(x)\,dx = \frac{\# \left\{ \lambda_i : \frac{\lambda_i(A)}{2\sqrt{N}} \in [a, b] \right\}}{N} \]
$\delta(x - x_0)$ is a unit point mass at $x_0$:
$$\int f(x)\delta(x - x_0)\,dx = f(x_0).$$

To each $A$, attach a probability measure:

$$\mu_{A,N}(x) = \frac{1}{N} \sum_{i=1}^{N} \delta \left( x - \frac{\lambda_i(A)}{2\sqrt{N}} \right)$$
$$\int_{a}^{b} \mu_{A,N}(x)\,dx = \frac{\# \left\{ \lambda_i : \frac{\lambda_i(A)}{2\sqrt{N}} \in [a, b] \right\}}{N}$$

$$k^{\text{th}} \text{ moment} = \frac{\sum_{i=1}^{N} \lambda_i(A)^k}{2^k N \frac{k}{2} + 1} = \frac{\text{Trace}(A^k)}{2^k N \frac{k}{2} + 1}.$$
Wigner’s Semi-Circle Law

Not most general case, gives flavor.

Wigner’s Semi-Circle Law

$N \times N$ real symmetric matrices, entries i.i.d.r.v. from a fixed $p(x)$ with mean 0, variance 1, and other moments finite. Then for almost all $A$, as $N \rightarrow \infty$

$$
\mu_{A,N}(x) \longrightarrow \begin{cases} 
\frac{2}{\pi} \sqrt{1 - x^2} & \text{if } |x| \leq 1 \\
0 & \text{otherwise.}
\end{cases}
$$
SKETCH OF PROOF: Eigenvalue Trace Lemma

Want to understand the eigenvalues of $A$, but it is the matrix elements that are chosen randomly and independently.

**Eigenvalue Trace Lemma**

Let $A$ be an $N \times N$ matrix with eigenvalues $\lambda_i(A)$. Then

$$\text{Trace}(A^k) = \sum_{n=1}^{N} \lambda_i(A)^k,$$

where

$$\text{Trace}(A^k) = \sum_{i_1=1}^{N} \cdots \sum_{i_k=1}^{N} a_{i_1 i_2} a_{i_2 i_3} \cdots a_{i_N i_1}.$$
SKETCH OF PROOF: Correct Scale

$$\text{Trace}(A^2) = \sum_{i=1}^{N} \lambda_i(A)^2.$$ 

By the Central Limit Theorem:

$$\text{Trace}(A^2) = \sum_{i=1}^{N} \sum_{j=1}^{N} a_{ij}a_{ji} = \sum_{i=1}^{N} \sum_{j=1}^{N} a_{ij}^2 \sim N^2$$

$$\sum_{i=1}^{N} \lambda_i(A)^2 \sim N^2$$

Gives $N\text{Ave}(\lambda_i(A)^2) \sim N^2$ or $\text{Ave}(\lambda_i(A)) \sim \sqrt{N}$. 
SKETCH OF PROOF: Averaging Formula

Recall $k$-th moment of $\mu_{A,N}(x)$ is $\text{Trace}(A^k)/2^k N^{k/2+1}$.

Average $k$-th moment is

$$\int \cdots \int \frac{\text{Trace}(A^k)}{2^k N^{k/2+1}} \prod_{i \leq j} p(a_{ij}) da_{ij}.$$ 

Proof by method of moments: Two steps

- Show average of $k$-th moments converge to moments of semi-circle as $N \to \infty$;
- Control variance (show it tends to zero as $N \to \infty$).
SKETCH OF PROOF: Averaging Formula for Second Moment

Substituting into expansion gives

\[ \frac{1}{2^2 N^2} \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} \sum_{i=1}^{N} \sum_{j=1}^{N} a_{ij}^2 \cdot p(a_{11}) da_{11} \cdots p(a_{NN}) da_{NN} \]

Integration factors as

\[ \int_{a_{ij}=-\infty}^{\infty} a_{ij}^2 p(a_{ij}) da_{ij} \cdot \prod_{(k,l) \neq (i,j)} \int_{a_{kl}=-\infty}^{\infty} p(a_{kl}) da_{kl} = 1. \]

Higher moments involve more advanced combinatorics (Catalan numbers).
SKETCH OF PROOF: Averaging Formula for Higher Moments

Higher moments involve more advanced combinatorics (Catalan numbers).

\[
\frac{1}{2^k N^{k/2+1}} \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} \sum_{i_1=1}^{N} \cdots \sum_{i_k=1}^{N} a_{i_1i_2} \cdots a_{i_ki_1} \cdot \prod_{i \leq j} p(a_{ij}) \, da_{ij}.
\]

Main term \(a_{i_\ell i_{\ell+1}}\)'s matched in pairs, not all matchings contribute equally (if did have Gaussian, see in Real Symmetric Palindromic Toeplitz matrices; interesting results for circulant ensembles (joint with Gene Kopp, Murat Kologlu).
Numerical examples

500 Matrices: Gaussian $400 \times 400$

$$p(x) = \frac{1}{\sqrt{2\pi}} e^{-x^2/2}$$
The eigenvalues of the Cauchy distribution are NOT semicircular.

**Cauchy Distribution:** $p(x) = \frac{1}{\pi(1+x^2)}$
GOE Conjecture:

As $N \to \infty$, the probability density of the spacing b/w consecutive normalized eigenvalues approaches a limit independent of $p$.

Until recently only known if $p$ is a Gaussian.

$$\text{GOE}(x) \approx \frac{\pi}{2} xe^{-\pi x^2/4}.$$
Numerical Experiment: Uniform Distribution

Let \( p(x) = \frac{1}{2} \) for \( |x| \leq 1 \).

The local spacings of the central 3/5 of the eigenvalues of 5000 300x300 uniform matrices, normalized in batches of 20.

5000: 300 × 300 uniform on \([-1, 1]\)
Let $p(x) = \frac{1}{\pi(1+x^2)}$. 

The local spacings of the central 3/5 of the eigenvalues of 5000 100x100 Cauchy matrices, normalized in batches of 20.
Cauchy Distribution

Let \( p(x) = \frac{1}{\pi(1+x^2)} \).

The local spacings of the central 3/5 of the eigenvalues of 5000 300x300 Cauchy matrices, normalized in batches of 20.
Random Graphs

Degree of a vertex = number of edges leaving the vertex. Adjacency matrix: \( a_{ij} = \) number of edges b/w Vertex \( i \) and Vertex \( j \).

\[
A = \begin{pmatrix}
0 & 0 & 1 & 1 \\
0 & 0 & 1 & 0 \\
1 & 1 & 0 & 2 \\
1 & 0 & 2 & 0
\end{pmatrix}
\]

These are Real Symmetric Matrices.
McKay’s Law (Kesten Measure) with $d = 3$

Density of Eigenvalues for $d$-regular graphs

$$f(x) = \begin{cases} \frac{d}{2\pi(d^2-x^2)} \sqrt{4(d-1) - x^2} & |x| \leq 2\sqrt{d-1} \\ 0 & \text{otherwise.} \end{cases}$$
McKay’s Law (Kesten Measure) with $d = 6$

Fat Thin: fat enough to average, thin enough to get something different than semi-circle (though as $d \to \infty$ recover semi-circle).
3-Regular Graph with 2000 Vertices: Comparison with the GOE

Spacings between eigenvalues of 3-regular graphs and the GOE:
Block Circulant Ensemble
(with Murat Koloğlu, Gene Kopp, Fred Strauch and Wentao Xiong)
The Ensemble of $m$-Block Circulant Matrices

Symmetric matrices periodic with period $m$ on wrapped diagonals, i.e., symmetric block circulant matrices.

8-by-8 real symmetric 2-block circulant matrix:

$$
\begin{pmatrix}
  c_0 & c_1 & c_2 & c_3 & c_4 & d_3 & d_2 & c_3 \\
  c_1 & d_0 & d_1 & d_2 & c_4 & d_3 & d_2 & c_3 \\
  c_2 & d_1 & c_0 & c_1 & c_2 & c_3 & d_1 & d_2 \\
  c_3 & d_2 & c_1 & d_0 & d_1 & d_2 & c_2 & c_3 \\
  c_4 & d_3 & c_2 & d_1 & c_0 & c_1 & c_2 & c_3 \\
  d_3 & d_4 & c_3 & d_2 & c_1 & d_0 & d_1 & d_2 \\
  c_2 & c_3 & c_4 & d_3 & c_2 & d_1 & c_0 & c_1 \\
  d_1 & d_2 & d_3 & d_4 & c_3 & d_2 & c_1 & d_0 
\end{pmatrix}
$$

Choose distinct entries i.i.d.r.v.
Oriented Matchings and Dualization

Compute moments of eigenvalue distribution (as $m$ stays fixed and $N \to \infty$) using the combinatorics of pairings. Rewrite:

\[
M_n(N) = \frac{1}{N^{n+1}} \sum_{1 \leq i_1, \ldots, i_n \leq N} \mathbb{E}(a_{i_1} a_{i_2} a_{i_3} \cdots a_{i_n})
\]

\[
= \frac{1}{N^{n+1}} \sum_{\sim} \eta(\sim) m_{d_1}(\sim) \cdots m_{d_l}(\sim).
\]

where the sum is over oriented matchings on the edges \{((1, 2), (2, 3), \ldots, (n, 1))\} of a regular $n$-gon.
Oriented Matchings and Dualization

**Figure:** An oriented matching in the expansion for $M_n(N) = M_6(8)$. 

\[
\begin{pmatrix}
    c_0 & c_1 & c_2 & c_3 & c_4 & d_3 & c_2 & d_1 \\
    c_1 & d_0 & d_1 & d_2 & d_3 & d_4 & c_3 & d_2 \\
    c_2 & d_1 & c_0 & c_1 & c_2 & c_3 & c_4 & d_3 \\
    c_3 & d_2 & c_1 & d_0 & d_1 & d_2 & d_3 & d_4 \\
    c_4 & d_3 & c_2 & d_1 & c_0 & c_1 & c_2 & c_3 \\
    d_3 & d_4 & c_3 & d_2 & c_1 & d_0 & d_1 & d_2 \\
    c_2 & c_3 & c_4 & d_3 & c_2 & d_1 & c_0 & c_1 \\
    d_1 & d_2 & d_3 & d_4 & c_3 & d_2 & c_1 & d_0
\end{pmatrix}
\]
Contributing Terms

As $N \to \infty$, the only terms that contribute to this sum are those in which the entries are matched in pairs and with opposite orientation.
Only Topology Matters

Think of pairings as topological identifications; the contributing ones give rise to orientable surfaces.

Contribution from such a pairing is $m^{-2g}$, where $g$ is the genus (number of holes) of the surface. Proof: combinatorial argument involving Euler characteristic.
Computing the Even Moments

**Theorem: Even Moment Formula**

\[ M_{2k} = \sum_{g=0}^{\lfloor k/2 \rfloor} \varepsilon_g(k) m^{-2g} + O_k \left( \frac{1}{N} \right), \]

with \( \varepsilon_g(k) \) the number of pairings of the edges of a \((2k)\)-gon giving rise to a genus \( g \) surface.

J. Harer and D. Zagier (1986) gave generating functions for the \( \varepsilon_g(k) \).
Harer and Zagier

\[ \sum_{g=0}^{\lfloor k/2 \rfloor} \varepsilon_g(k) r^{k+1-2g} = (2k - 1)!! \ c(k, r) \]

where

\[ 1 + 2 \sum_{k=0}^{\infty} c(k, r) x^{k+1} = \left( \frac{1 + x}{1 - x} \right)^r. \]

Thus, we write

\[ M_{2k} = m^{-(k+1)} (2k - 1)!! \ c(k, m). \]
A multiplicative convolution and Cauchy’s residue formula yield the characteristic function of the distribution.

\[
\phi(t) = \sum_{k=0}^{\infty} \frac{(it)^{2k} M_{2k}}{(2k)!} = \frac{1}{m} \sum_{k=0}^{\infty} \frac{(-t^2/2m)^k}{k!} c(k, m)
\]

\[
= \frac{1}{2\pi i m} \oint_{|z|=2} \frac{1}{2z^{-1}} \left( \left( \frac{1 + z^{-1}}{1 - z^{-1}} \right)^m - 1 \right) e^{-t^2 z / 2m} \frac{dz}{z}
\]

\[
= \frac{1}{m} e^{-t^2 / 2m} \sum_{\ell=1}^{m} \binom{m}{\ell} \frac{1}{(\ell - 1)!} \left( \frac{-t^2}{m} \right)^{\ell-1}
\]
Fourier transform and algebra yields

**Theorem: Koloğlu, Kopp and Miller**

The limiting spectral density function $f_m(x)$ of the real symmetric $m$-block circulant ensemble is given by the formula

$$f_m(x) = \frac{e^{-\frac{mx^2}{2}}}{\sqrt{2\pi m}} \sum_{r=0}^{m} \frac{1}{(2r)!} \sum_{s=0}^{m-r} \binom{m}{r+s+1} \frac{(2r+2s)!}{(r+s)!s!} \left(-\frac{1}{2}\right)^s (mx^2)^r.$$

As $m \to \infty$, the limiting spectral densities approach the semicircle distribution.

Introduction to $L$-Functions
Riemann Zeta Function

\[ \zeta(s) = \sum_{n=1}^{\infty} \frac{1}{n^s} = \prod_{\rho \text{ prime}} \left(1 - \frac{1}{\rho^s}\right)^{-1}, \quad \text{Re}(s) > 1. \]

**Functional Equation:**

\[ \xi(s) = \Gamma\left(\frac{s}{2}\right)\pi^{-\frac{s}{2}} \zeta(s) = \xi(1 - s). \]

**Riemann Hypothesis (RH):**

All non-trivial zeros have \( \text{Re}(s) = \frac{1}{2} \); can write zeros as \( \frac{1}{2} + i\gamma \).

**Observation:** Spacings b/w zeros appear same as b/w eigenvalues of Complex Hermitian matrices \( \overline{A^T} = A \).
General $L$-functions

$$L(s, f) = \sum_{n=1}^{\infty} \frac{a_f(n)}{n^s} = \prod_{p \text{ prime}} L_p(s, f)^{-1}, \quad \text{Re}(s) > 1.$$ 

**Functional Equation:**

$$\Lambda(s, f) = \Lambda_\infty(s, f)L(s, f) = \Lambda(1 - s, f).$$

**Generalized Riemann Hypothesis (RH):**

All non-trivial zeros have $\text{Re}(s) = \frac{1}{2}$; can write zeros as $\frac{1}{2} + i\gamma$.

**Observation:** Spacings b/w zeros appear same as b/w eigenvalues of Complex Hermitian matrices $\bar{A}^T = A$. 
Zeros of $\zeta(s)$ vs GUE

70 million spacings b/w adjacent zeros of $\zeta(s)$, starting at the $10^{20}\text{th}$ zero (from Odlyzko).
Explicit Formula (Contour Integration)

\[-\frac{\zeta'(s)}{\zeta(s)} = -\frac{d}{ds} \log \zeta(s) = -\frac{d}{ds} \log \prod_p (1 - p^{-s})^{-1}\]
Explicit Formula (Contour Integration)

\[-\frac{\zeta'(s)}{\zeta(s)} = -\frac{d}{ds} \log \zeta(s) = -\frac{d}{ds} \log \left( \prod_p (1 - p^{-s})^{-1} \right) = \frac{d}{ds} \sum_p \log (1 - p^{-s}) = \sum_p \frac{\log p \cdot p^{-s}}{1 - p^{-s}} = \sum_p \frac{\log p}{p^s} + \text{Good}(s).\]
Explicit Formula (Contour Integration)

\[- \frac{\zeta'(s)}{\zeta(s)} = - \frac{d}{ds} \log \zeta(s) = - \frac{d}{ds} \log \prod_p (1 - p^{-s})^{-1} \]

\[= \frac{d}{ds} \sum_p \log (1 - p^{-s}) \]

\[= \sum_p \frac{\log p \cdot p^{-s}}{1 - p^{-s}} = \sum_p \frac{\log p}{p^s} + \text{Good}(s). \]

Contour Integration:

\[\int - \frac{\zeta'(s)}{\zeta(s)} \frac{x^s}{s} \, ds \quad \text{vs} \quad \sum_p \log p \int \left(\frac{x}{p}\right)^s \frac{ds}{s}. \]
Explicit Formula (Contour Integration)

\[- \frac{\zeta'(s)}{\zeta(s)} = - \frac{d}{ds} \log \zeta(s) = - \frac{d}{ds} \log \prod_p (1 - p^{-s})^{-1} \]

\[= \frac{d}{ds} \sum_p \log (1 - p^{-s}) \]

\[= \sum_p \frac{\log p \cdot p^{-s}}{1 - p^{-s}} = \sum_p \frac{\log p}{p^s} + \text{Good}(s). \]

Contour Integration:

\[\int - \frac{\zeta'(s)}{\zeta(s)} \phi(s) ds \quad \text{vs} \quad \sum_p \log p \int \phi(s)p^{-s} ds.\]
Explicit Formula (Contour Integration)

\[-\frac{\zeta'(s)}{\zeta(s)} = -\frac{d}{ds} \log \zeta(s) = -\frac{d}{ds} \log \prod_p (1 - p^{-s})^{-1}\]

\[= \frac{d}{ds} \sum_p \log (1 - p^{-s})\]

\[= \sum_p \frac{\log p \cdot p^{-s}}{1 - p^{-s}} = \sum_p \frac{\log p}{p^s} + \text{Good}(s).\]

Contour Integration (see Fourier Transform arising):

\[\int -\frac{\zeta'(s)}{\zeta(s)} \phi(s) ds \text{ vs } \sum_p \log p \int \phi(s) e^{-\sigma \log p} e^{-it \log p} ds.\]

Knowledge of zeros gives info on coefficients.
Explicit Formula: Examples

Riemann Zeta Function: Let $\sum \rho$ denote the sum over the zeros of $\zeta(s)$ in the critical strip, $g$ an even Schwartz function of compact support and $\phi(r) = \int_{-\infty}^{\infty} g(u) e^{iru} du$. Then

$$\sum_{\rho} \phi(\gamma_{\rho}) = 2\phi \left( \frac{i}{2} \right) - \sum_{p} \sum_{k=1}^{\infty} \frac{2 \log p}{p^{k/2}} g(k \log p)$$

$$ + \frac{1}{\pi} \int_{-\infty}^{\infty} \left( \frac{1}{iy} - \frac{1}{2} + \frac{\Gamma' \left( \frac{iy}{2} + \frac{5}{4} \right)}{\Gamma \left( \frac{iy}{2} + \frac{5}{4} \right)} - \frac{1}{2} \log \pi \right) \phi(y) \, dy.$$
Explicit Formula: Examples

**Dirichlet $L$-functions:** Let $h$ be an even Schwartz function and $L(s, \chi) = \sum_n \chi(n)/n^s$ a Dirichlet $L$-function from a non-trivial character $\chi$ with conductor $m$ and zeros $\rho = \frac{1}{2} + i\gamma_{\chi}$; if the Generalized Riemann Hypothesis is true then $\gamma \in \mathbb{R}$. Then

$$\sum_{\rho} h\left(\gamma_{\rho} \frac{\log(m/\pi)}{2\pi}\right) = \int_{-\infty}^{\infty} h(y)\,dy$$

$$-2 \sum_{p} \frac{\log p}{\log(m/\pi)} \hat{h}\left(\frac{\log p}{\log(m/\pi)}\right) \frac{\chi(p)}{p^{1/2}}$$

$$-2 \sum_{p} \frac{\log p}{\log(m/\pi)} \hat{h}\left(2 \frac{\log p}{\log(m/\pi)}\right) \frac{\chi^2(p)}{p} + O\left(\frac{1}{\log m}\right).$$
Explicit Formula: Examples

Cuspidal Newforms: Let $\mathcal{F}$ be a family of cuspidal newforms (say weight $k$, prime level $N$ and possibly split by sign) $L(s, f) = \sum_n \lambda_f(n)/n^s$. Then

$$
\frac{1}{|\mathcal{F}|} \sum_{f \in \mathcal{F}} \sum_{\gamma_f} \phi \left( \frac{\log R}{2\pi} \gamma_f \right) = \hat{\phi}(0) + \frac{1}{2} \phi(0) - \frac{1}{|\mathcal{F}|} \sum_{f \in \mathcal{F}} P(f; \phi) + O \left( \frac{\log \log R}{\log R} \right)
$$

$$
P(f; \phi) = \sum_{p \nmid N} \lambda_f(p) \hat{\phi} \left( \frac{\log p}{\log R} \right) \frac{2 \log p}{\sqrt{p} \log R}.
$$
Measures of Spacings: \( n \)-Level Correlations

\[ \{ \alpha_j \} \text{ increasing sequence, box } B \subset \mathbb{R}^{n-1}. \]

**n-level correlation**

\[
\lim_{N \to \infty} \frac{\# \left\{ \left( \alpha_{j_1} - \alpha_{j_2}, \ldots, \alpha_{j_{n-1}} - \alpha_{j_n} \right) \in B, j_i \neq j_k \right\}}{N}
\]

(Instead of using a box, can use a smooth test function.)
Measures of Spacings: \( n \)-Level Correlations

\[ \{\alpha_j\} \text{ increasing sequence, box } B \subset \mathbb{R}^{n-1}. \]

1. Normalized spacings of \( \zeta(s) \) starting at \( 10^{20} \) (Odlyzko).

2. 2 and 3-correlations of \( \zeta(s) \) (Montgomery, Hejhal).

3. \( n \)-level correlations for all automorphic cuspidal \( L \)-functions (Rudnick-Sarnak).

4. \( n \)-level correlations for the classical compact groups (Katz-Sarnak).

5. Insensitive to any finite set of zeros.
Measures of Spacings: \( n \)-Level Density and Families

\[ \phi(x) := \prod_i \phi_i(x_i), \quad \phi_i \text{ even Schwartz functions whose Fourier Transforms are compactly supported.} \]

\[ n\text{-level density} \]

\[ D_{n,f}(\phi) = \sum_{j_1, \ldots, j_n \text{ distinct}} \phi_1 \left( L_f \gamma_f^{(j_1)} \right) \cdots \phi_n \left( L_f \gamma_f^{(j_n)} \right) \]
Measures of Spacings: \( n \)-Level Density and Families

\[
\phi(x) := \prod_i \phi_i(x_i), \quad \phi_i \text{ even Schwartz functions whose Fourier Transforms are compactly supported.}
\]

\( n \)-level density

\[
D_{n,f}(\phi) = \sum_{j_1, \ldots, j_n \text{ distinct}} \phi_1\left(L_f \gamma_f^{(j_1)}\right) \cdots \phi_n\left(L_f \gamma_f^{(j_n)}\right)
\]

1. Individual zeros contribute in limit.
2. Most of contribution is from low zeros.
3. Average over similar curves (family).
Measures of Spacings: \(n\)-Level Density and Families

\[ \phi(x) := \prod_i \phi_i(x_i), \phi_i \text{ even Schwartz functions whose Fourier Transforms are compactly supported.} \]

\[ n\text{-level density} \]

\[ D_{n,f}(\phi) = \sum_{j_1, \ldots, j_n \text{ distinct}} \phi_1 \left( L_f \gamma_f^{(j_1)} \right) \cdots \phi_n \left( L_f \gamma_f^{(j_n)} \right) \]

1. Individual zeros contribute in limit.
2. Most of contribution is from low zeros.
3. Average over similar curves (family).

**Katz-Sarnak Conjecture**

For a ‘nice’ family of \(L\)-functions, the \(n\)-level density depends only on a symmetry group attached to the family.
Normalization of Zeros

Local (hard, use $C_f$) vs Global (easier, use $\log C = |\mathcal{F}_N|^{-1} \sum_{f \in \mathcal{F}_N} \log C_f$). **Hope:** $\phi$ a good even test function with compact support, as $|\mathcal{F}| \to \infty$,

$$
\frac{1}{|\mathcal{F}_N|} \sum_{f \in \mathcal{F}_N} D_{n,f}(\phi) = \frac{1}{|\mathcal{F}_N|} \sum_{f \in \mathcal{F}_N} \sum_{j_1, \ldots, j_n} \prod_i \phi_i \left( \frac{\log C_f}{2\pi} \gamma_E^{(j_i)} \right)
$$

$$
\to \int \cdots \int \phi(x) W_{n,G(\mathcal{F})}(x) dx.
$$

Katz-Sarnak Conjecture

As $C_f \to \infty$ the behavior of zeros near $1/2$ agrees with $N \to \infty$ limit of eigenvalues of a classical compact group.
### 1-Level Densities

The Fourier Transforms for the 1-level densities are

\[
\hat{W}_{1,\text{SO(even)}}(u) = \delta_0(u) + \frac{1}{2} \eta(u)
\]

\[
\hat{W}_{1,\text{SO}}(u) = \delta_0(u) + \frac{1}{2}
\]

\[
\hat{W}_{1,\text{SO(odd)}}(u) = \delta_0(u) - \frac{1}{2} \eta(u) + 1
\]

\[
\hat{W}_{1,\text{Sp}}(u) = \delta_0(u) - \frac{1}{2} \eta(u)
\]

\[
\hat{W}_{1,\text{U}}(u) = \delta_0(u)
\]

where \(\delta_0(u)\) is the Dirac Delta functional and

\[
\eta(u) = \begin{cases} 
1 & \text{if } |u| < 1 \\
\frac{1}{2} & \text{if } |u| = 1 \\
0 & \text{if } |u| > 1 
\end{cases}
\]
Correspondences

Similarities between $L$-Functions and Nuclei:

- Zeros $\leftrightarrow$ Energy Levels
- Schwartz test function $\rightarrow$ Neutron
- Support of test function $\leftrightarrow$ Neutron Energy.
Results
Some Number Theory Results

- **Orthogonal**: Iwaniec-Luo-Sarnak, Ricotta-Royer: 1-level density for holomorphic even weight $k$ cuspidal newforms of square-free level $N$ (SO(even) and SO(odd) if split by sign).

- **Symplectic**: Rubinstein, Gao, Levinson-Miller, and Entin, Roddity-Gershon and Rudnick: $n$-level densities for twists $L(s, \chi_d)$ of the zeta-function.

- **Unitary**: Fiorilli-Miller, Hughes-Rudnick: Families of Primitive Dirichlet Characters.

- **Orthogonal**: Miller, Young: One and two-parameter families of elliptic curves.
Main Tools

1. **Control of conductors**: Usually monotone, gives scale to study low-lying zeros.

2. **Explicit Formula**: Relates sums over zeros to sums over primes.

Applications of $n$-level density

One application: bounding the order of vanishing at the central point.
Average rank · $\phi(0) \leq \int \phi(x) W_{G(F)}(x) dx$ if $\phi$ non-negative.
Applications of \( n \)-level density

One application: bounding the order of vanishing at the central point.
Average rank \( \cdot \phi(0) \leq \int \phi(x) W_{G(F)}(x) dx \) if \( \phi \) non-negative.
Can also use to bound the percentage that vanish to order \( r \) for any \( r \).

**Theorem (Miller, Hughes-Miller)**

*Using \( n \)-level arguments, for the family of cuspidal newforms of prime level \( N \to \infty \) (split or not split by sign), for any \( r \) there is a \( c_r \) such that probability of at least \( r \) zeros at the central point is at most \( c_n r^{-n} \).*

Better results using 2-level than Iwaniec-Luo-Sarnak using the 1-level for \( r \geq 5 \).
Identifying the Symmetry Groups

- Often an analysis of the monodromy group in the function field case suggests the answer.

- Tools: Explicit Formula, Orthogonality of Characters / Petersson Formula.

- How to identify symmetry group in general? One possibility is by the signs of the functional equation:

  **Folklore Conjecture:** If all signs are even and no corresponding family with odd signs, Symplectic symmetry; otherwise SO(even). (False!)
Explicit Formula

- $\pi$: cuspidal automorphic representation on $\text{GL}_n$.
- $Q_\pi > 0$: analytic conductor of $L(s, \pi) = \sum \lambda_\pi(n)/n^s$.
- By GRH the non-trivial zeros are $\frac{1}{2} + i\gamma_\pi,j$.
- Satake parameters $\{\alpha_{\pi,i}(p)\}_{i=1}^n$;
  $\lambda_\pi(p^\nu) = \sum_{i=1}^n \alpha_{\pi,i}(p)^\nu$.
- $L(s, \pi) = \sum_n \frac{\lambda_\pi(n)}{n^s} = \prod_p \prod_{i=1}^n (1 - \alpha_{\pi,i}(p)p^{-s})^{-1}$.

$$\sum_j g \left( \gamma_\pi,j \frac{\log Q_\pi}{2\pi} \right) = \hat{g}(0) - 2 \sum_{p, \nu} \hat{g} \left( \nu \frac{\log p}{\log Q_\pi} \right) \frac{\lambda_\pi(p^\nu) \log p}{p^\nu/2 \log Q_\pi}$$
1-Level Density

Assuming conductors constant in family $\mathcal{F}$, have to study

$$\lambda_f(p^\nu) = \alpha_{f,1}(p)^\nu + \cdots + \alpha_{f,n}(p)^\nu$$

$$S_1(\mathcal{F}) = -2 \sum_p \hat{g} \left( \frac{\log p}{\log R} \right) \frac{\log p}{\sqrt{p} \log R} \left[ \frac{1}{|\mathcal{F}|} \sum_{f \in \mathcal{F}} \lambda_f(p) \right]$$

$$S_2(\mathcal{F}) = -2 \sum_p \hat{g} \left( 2 \frac{\log p}{\log R} \right) \frac{\log p}{p \log R} \left[ \frac{1}{|\mathcal{F}|} \sum_{f \in \mathcal{F}} \lambda_f(p^2) \right]$$

The corresponding classical compact group is determined by

$$\frac{1}{|\mathcal{F}|} \sum_{f \in \mathcal{F}} \lambda_f(p^2) = c_{\mathcal{F}} = \begin{cases} 0 & \text{Unitary} \\ 1 & \text{Symplectic} \\ -1 & \text{Orthogonal.} \end{cases}$$
Some Results: Rankin-Selberg Convolution of Families

Symmetry constant: $c_\mathcal{L} = 0$ (resp, 1 or -1) if family $\mathcal{L}$ has unitary (resp, symplectic or orthogonal) symmetry.

Rankin-Selberg convolution: Satake parameters for $\pi_1,p \times \pi_2,p$ are

$$\{ \alpha_{\pi_1 \times \pi_2}(k) \}_{k=1}^{nm} = \{ \alpha_{\pi_1}(i) \cdot \alpha_{\pi_2}(j) \}_{1 \leq i \leq n, 1 \leq j \leq m}.$$

Theorem (Dueñez-Miller)

If $\mathcal{F}$ and $\mathcal{G}$ are nice families of $L$-functions, then

$$c_{\mathcal{F} \times \mathcal{G}} = c_\mathcal{F} \cdot c_\mathcal{G}.$$

Breaks analysis of compound families into simple ones.
Takeaways

Very similar to Central Limit Theorem.

- Universal behavior: main term controlled by first two moments of Satake parameters, agrees with RMT.

- First moment zero save for families of elliptic curves.

- Higher moments control convergence and can depend on arithmetic of family.
Elliptic Curves: First Zero Above Central Point
(With E. Dueñez, D. K. Huynh, J. P. Keating, N. Snaith)
Theoretical results

**Theorem: M– ’04**

For small support, one-param family of rank $r$ over $\mathbb{Q}(T)$:

$$
\lim_{N \to \infty} \frac{1}{|F_N|} \sum_{E_t \in F_N} \sum_{j} \varphi \left( \frac{\log C_{E_t}}{2\pi} \gamma_{E_t,j} \right) = \int \varphi(x) \rho_G(x) \, dx + r \varphi(0)
$$

where $G = \begin{cases} 
\text{SO(odd)} & \text{if half odd} \\
\text{SO(even)} & \text{if all even} \\
\text{weighted average} & \text{otherwise.}
\end{cases}$

Supports Katz-Sarnak, B-SD, and Independent model in limit.

**Independent Model:**

$$
A_{2N,2r} = \left\{ \begin{pmatrix} I_{2r} \times 2r \\ g \end{pmatrix} : g \in \text{SO}(2N - 2r) \right\}.
$$

Summary of Data

- The repulsion of the low-lying zeros increased with increasing rank, and was present even for rank 0 curves.

- As the conductors increased, the repulsion decreased.

- Statistical tests failed to reject the hypothesis that, on average, the first three zeros were all repelled equally (i.e., shifted by the same amount).
**Spacings b/w Norm Zeros: Rank 0 One-Param Families over \( \mathbb{Q}(T) \)**

New Model for Finite Conductors

- Replace conductor $N$ with $N_{\text{effective}}$.
  - Arithmetic info, predict with $L$-function Ratios Conj.
  - Do the number theory computation.

- Excised Orthogonal Ensembles.
  - $L(1/2, E)$ discretized.
  - Study matrices in $SO(2N_{\text{eff}})$ with $|\Lambda_A(1)| \geq ce^N$.

- Painlevé VI differential equation solver.
  - Use explicit formulas for densities of Jacobi ensembles.
  - Key input: Selberg-Aomoto integral for initial conditions.
Modeling lowest zero of $L_{E_{11}}(s, \chi_d)$ with $0 < d < 400,000$

Lowest zero for $L_{E_{11}}(s, \chi_d)$ (bar chart), lowest eigenvalue of SO(2N) with $N_{\text{eff}}$ (solid), standard $N_0$ (dashed).
Modeling lowest zero of $L_{E_{11}}(s, \chi_d)$ with $0 < d < 400,000$

Lowest zero for $L_{E_{11}}(s, \chi_d)$ (bar chart); lowest eigenvalue of $\text{SO}(2N)$: $N_{\text{eff}} = 2$ (solid) with discretisation, and $N_{\text{eff}} = 2.32$ (dashed) without discretisation.
History of the Ratios Conjecture

- Farmer (1993): Considered

\[ \int_0^T \frac{\zeta(s + \alpha) \zeta(1 - s + \beta)}{\zeta(s + \gamma) \zeta(1 - s + \delta)} \ dt, \]

conjectured (for appropriate values)

\[ T^{(\alpha + \delta)(\beta + \gamma)} \frac{\zeta(1 - \alpha - \beta)}{\zeta(\alpha + \beta)(\gamma + \delta)} \]

- Conrey-Farmer-Zirnbauer (2007): conjecture formulas for averages of products of \( L \)-functions over families:

\[ R_F = \sum_{f \in F} \omega_f \frac{L\left(\frac{1}{2} + \alpha, f\right)}{L\left(\frac{1}{2} + \gamma, f\right)}. \]
Uses of the Ratios Conjecture

- **Applications:**
  - $n$-level correlations and densities;
  - mollifiers;
  - moments;
  - vanishing at the central point;

- **Advantages:**
  - RMT models often add arithmetic ad hoc;
  - predicts lower order terms, often to square-root level.
Inputs for 1-level density

- **Approximate Functional Equation:**

\[
L(s, f) = \sum_{m \leq x} \frac{a_m}{m^s} + \epsilon \Xi_L(s) \sum_{n \leq y} \frac{a_n}{n^{1-s}};
\]

- \(\epsilon\) sign of the functional equation,
- \(\Xi_L(s)\) ratio of \(\Gamma\)-factors from functional equation.

- **Explicit Formula:** \(g\) Schwartz test function,

\[
\sum_{f \in \mathcal{F}} \sum_{\gamma} \omega_f g \left( \gamma \frac{\log N_f}{2\pi} \right) = \frac{1}{2\pi i} \int_{(c)} - \int_{(1-c)} R'_\mathcal{F}(\cdots)g(\cdots)
\]

- \(R'_\mathcal{F}(r) = \frac{\partial}{\partial \alpha} R_{\mathcal{F}}(\alpha, \gamma)\bigg|_{\alpha=\gamma=r}\).
Procedure (Recipe)

- Use approximate functional equation to expand numerator.
- Expand denominator by generalized Mobius function: cusp form

\[
\frac{1}{L(s, f)} = \sum_{h} \frac{\mu_f(h)}{h^s},
\]

where \( \mu_f(h) \) is the multiplicative function equaling 1 for \( h = 1 \), \(-\lambda_f(p)\) if \( n = p \), \( \chi_0(p) \) if \( h = p^2 \) and 0 otherwise.
- Execute the sum over \( \mathcal{F} \), keeping only main (diagonal) terms.
- Extend the \( m \) and \( n \) sums to infinity (complete the products).
- Differentiate with respect to the parameters.
Procedure (‘Illegal Steps’)

- Use approximate functional equation to expand numerator.
- Expand denominator by generalized Mobius function: cusp form

\[
\frac{1}{L(s, f)} = \sum_{h} \frac{\mu_f(h)}{h^s},
\]

where \(\mu_f(h)\) is the multiplicative function equaling 1 for \(h = 1\), \(-\lambda_f(p)\) if \(n = p\), \(\chi_0(p)\) if \(h = p^2\) and 0 otherwise.

- Execute the sum over \(\mathcal{F}\), keeping only main (diagonal) terms.
- Extend the \(m\) and \(n\) sums to infinity (complete the products).
- Differentiate with respect to the parameters.
1-Level Prediction from Ratio’s Conjecture

\[
A_E(\alpha, \gamma) = Y_E^{-1}(\alpha, \gamma) \times \prod_{p \mid M} \left( \sum_{m=0}^{\infty} \left( \frac{\lambda(p^m)\omega_E^m}{p^m(1/2+\alpha)} - \frac{\lambda(p)}{p^{1/2+\gamma}} \frac{\lambda(p^m)\omega_E^{m+1}}{p^m(1/2+\alpha)} \right) \right) \times
\prod_{p \not\mid M} \left( 1 + \frac{p}{p+1} \left( \sum_{m=1}^{\infty} \frac{\lambda(p^{2m})}{p^{m(1+2\alpha)}} - \frac{\lambda(p)}{p^{1+\alpha+\gamma}} \sum_{m=0}^{\infty} \frac{\lambda(p^{2m+1})}{p^{m(1+2\alpha)}} \right) + \frac{1}{p^{1+2\gamma}} \sum_{m=0}^{\infty} \frac{\lambda(p^{2m})}{p^{m(1+2\alpha)}} \right)
\]

where

\[
Y_E(\alpha, \gamma) = \frac{\zeta(1 + 2\gamma)L_E(\text{sym}^2, 1 + 2\alpha)}{\zeta(1 + \alpha + \gamma)L_E(\text{sym}^2, 1 + \alpha + \gamma)}.
\]

Huynh, Morrison and Miller confirmed Ratios’ prediction, which is
1-Level Prediction from Ratio’s Conjecture

\[
\frac{1}{X^*} \sum_{d \in \mathcal{F}(X)} \sum_{\gamma_d} g\left(\frac{\gamma_d L}{\tau}\right)
\]

\[
= \frac{1}{2 LX^*} \int_{-\infty}^{\infty} g(\tau) \sum_{d \in \mathcal{F}(X)} \left[ 2 \log \left( \frac{\sqrt{M}|d|}{2\pi} \right) + \frac{\Gamma'(1 + \frac{i\pi \tau}{L})}{\Gamma} + \frac{\Gamma'(1 - \frac{i\pi \tau}{L})}{\Gamma} \right] d\tau
\]

\[
+ \frac{1}{L} \sum_{k=0}^{\infty} \int_{-\infty}^{\infty} g(\tau) \frac{\log M}{M(k+1)(1+\frac{i\pi \tau}{L})} d\tau + \frac{1}{L} \int_{-\infty}^{\infty} g(\tau) \sum_{p \mid M} \frac{\log p}{p+1} \sum_{k=0}^{\infty} \frac{\lambda(p^{2k+2}) - \lambda(p^{2k})}{p^{(k+1)(1+\frac{2i\pi \tau}{L})}} d\tau
\]

\[
- \frac{1}{LX^*} \int_{-\infty}^{\infty} g(\tau) \sum_{d \in \mathcal{F}(X)} \left[ \left( \frac{\sqrt{M}|d|}{2\pi} \right)^{-2i\pi \tau/L} \frac{\Gamma(1 - \frac{i\pi \tau}{L})}{\Gamma(1 + \frac{i\pi \tau}{L})} \frac{\zeta(1 + \frac{2i\pi \tau}{L}) L_E(\text{sym}^2, 1 - \frac{2i\pi \tau}{L})}{L_E(\text{sym}^2, 1)} \right] d\tau + O(X^{-1/2+\varepsilon});
\]
Numerics (J. Stopple): 1,003,083 negative fundamental discriminants $-d \in [10^{12}, 10^{12} + 3.3 \cdot 10^6]$
Cuspidal Maass Forms
(Joint with Levent Alpoge)
Maass Forms

**Definition: Maass Forms**

A Maass form on a group $\Gamma \subset \text{PSL}(2, \mathbb{R})$ is a function $f : \mathcal{H} \rightarrow \mathbb{R}$ which satisfies:

1. $f(\gamma z) = f(z)$ for all $\gamma \in \Gamma$,
2. $f$ vanishes at the cusps of $\Gamma$, and
3. $\Delta f = \lambda f$ for some $\lambda = s(1 - s) > 0$, where

$$\Delta = -y^2 \left( \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right)$$

is the Laplace-Beltrami operator on $\mathcal{H}$.

- Coefficients contain information about partitions.
- For full modular group, $s = 1/2 + it_j$ with $t_j \in \mathbb{R}$. 
Write Fourier expansion of Maass form $u_j$ as

$$u_j(z) = \cosh(t_j) \sum_{n \neq 0} \sqrt{y} \lambda_j(n) K_{it_j}(2\pi |n|y) e^{2\pi inx}.$$ 

Define $L$-function attached to $u_j$ as

$$L(s, u_j) = \sum_{n \geq 1} \frac{\lambda_j(n)}{n^s} = \prod_p \left(1 - \frac{\alpha_j(p)}{p^s}\right)^{-1} \left(1 - \frac{\beta_j(p)}{p^s}\right)^{-1}$$

where $\alpha_j(p) + \beta_j(p) = \lambda_j(p), \quad \alpha_j(p)\beta_j(p) = 1, \quad \lambda_j(1) = 1.$

Also,

$$\lambda_j(p) \ll p^{7/64}.$$
Kuznetsov Trace Formula

\[
\sum_j \frac{h(t_j)}{\|u_j\|^2} \lambda_j(m) \overline{\lambda_j(n)} + \frac{1}{4\pi} \int_{\mathbb{R}} \frac{\tau(m, r) \tau(n, r)}{\cosh(\pi r)} \frac{h(r)}{\cosh(\pi r)} \, dr = \\
\delta_{n, m} \int_{\mathbb{R}} r \tanh(r) h(r) \, dr + \frac{2i}{\pi} \sum_{c \geq 1} \frac{S(n, m; c)}{c} \int_{\mathbb{R}} J_{ir} \left( \frac{4\pi \sqrt{mn}}{c} \right) \frac{h(r) r}{\cosh(\pi r)} \, dr
\]

where

\[
\tau(m, r) = \pi^{\frac{1}{2} + ir} \Gamma(1/2 + ir)^{-1} \zeta(1 + 2ir)^{-1} n^{-\frac{1}{2}} \sum_{ab = |m|} \left( \frac{a}{b} \right)^{ir}.
\]

\[
S(n, m; c) = \sum_{0 \leq x \leq c-1, \gcd(x, c) = 1} e^{2\pi i (nx + mx^*) / c}
\]

\[
J_{ir}(x) = \sum_{m=0}^{\infty} \frac{(-1)^m}{m! \Gamma(m + ir + 1)} \left( \frac{1}{2} x \right)^{2m + ir}.
\]
Main Result

Theorem (Alpoge-Miller 2013)
For \( h_T(r) = \frac{r}{T} h(ir/T) / \sinh(\pi r/T) \) the Katz-Sarnak conjecture holds for level 1 cuspidal Maass forms for test functions whose Fourier transform is supported in \((-4/3, 4/3)\).

- Write \( \int_{-\infty}^{\infty} J_{2ir}(X) \frac{r h_T(r)}{\cosh(\pi r)} dr \) as sum of \( J_{2k+1}(X) \) and \( h_T \) at imaginary arguments and \( J_{2kT}(X) \) and \( h \) at \( k \).

- Bound contributions from sums. Apply Poisson summation, analyze, and Poisson summation again.

- Key steps: Taylor expanding, Fourier transform identities relating differentiation and multiplication.
Cuspidal Newforms
(Joint with C. Hughes, G. Iyer, N. Triantafillou)
Modular Form Preliminaries

\[ \Gamma_0(N) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} : ad - bc = 1, c \equiv 0(N) \right\} \]

If \( f \) is a weight \( k \) holomorphic cuspform of level \( N \) if

\[ \forall \gamma \in \Gamma_0(N), \quad f(\gamma z) = (cz + d)^k f(z). \]

- Fourier Expansion: \( f(z) = \sum_{n=1}^{\infty} a_f(n) e^{2\pi iz} \),
  \( L(s, f) = \sum_{n=1}^{\infty} a_n n^{-s} \).
- Petersson Norm: \( \langle f, g \rangle = \int_{\Gamma_0(N) \backslash \mathbb{H}} f(z) \overline{g(z)} y^{k-2} \, dx \, dy \).
- Normalized coefficients:
  \[ \psi_f(n) = \sqrt{\frac{\Gamma(k-1)}{(4\pi n)^{k-1}} \frac{1}{\|f\|}} a_f(n). \]
Modular Form Preliminaries: Petersson Formula

$B_k(N)$ an orthonormal basis for weight $k$ level $N$. Define

$$\Delta_{k,N}(m, n) = \sum_{f \in B_k(N)} \psi_f(m) \overline{\psi}_f(n).$$

Petersson Formula

$$\Delta_{k,N}(m, n) = 2\pi i^k \sum_{c \equiv 0(N)} \frac{S(m, n, c)}{c} J_{k-1} \left(4\pi \sqrt{mn} c \right) + \delta(m, n).$$
2-Level Density

\[ \int_{x_1=2}^{R^\sigma} \int_{x_2=2}^{R^\sigma} \phi \left( \frac{\log x_1}{\log R} \right) \phi \left( \frac{\log x_2}{\log R} \right) J_{k-1} \left( 4\pi \frac{\sqrt{m^2 x_1 x_2 N}}{c} \right) \frac{dx_1 dx_2}{\sqrt{x_1 x_2}} \]

Change of variables and Jacobian:

\[
\begin{align*}
U_2 &= x_1 x_2 \\
U_1 &= x_1 \\
X_2 &= \frac{u_2}{u_1} \\
X_1 &= u_1
\end{align*}
\]

\[
\left| \frac{\partial x}{\partial u} \right| = \left| \begin{array}{cc}
1 & 0 \\
\frac{u_2}{u_1^2} & \frac{1}{u_1}
\end{array} \right| = \frac{1}{u_1}.
\]

Left with

\[
\int \int \phi \left( \frac{\log u_1}{\log R} \right) \phi \left( \frac{\log \left( \frac{u_2}{u_1} \right)}{\log R} \right) \frac{1}{\sqrt{u_2}} J_{k-1} \left( 4\pi \frac{\sqrt{m^2 u_2 N}}{c} \right) \frac{du_1 du_2}{u_1}
\]
2-Level Density

Changing variables, $u_1$-integral is

$$\int_{w_1 = \frac{\log u_2}{\log R} - \sigma}^{\sigma} \hat{\phi}(w_1) \hat{\phi} \left( \frac{\log u_2}{\log R} - w_1 \right) \, dw_1.$$  

Support conditions imply

$$\Psi_2 \left( \frac{\log u_2}{\log R} \right) = \int_{w_1 = -\infty}^{\infty} \hat{\phi}(w_1) \hat{\phi} \left( \frac{\log u_2}{\log R} - w_1 \right) \, dw_1.$$  

Substituting gives

$$\int_{u_2 = 0}^{\infty} J_{k-1} \left( 4\pi \frac{\sqrt{m^2 u_2 N}}{c} \right) \psi_2 \left( \frac{\log u_2}{\log R} \right) \frac{d u_2}{\sqrt{u_2}}.$$

$n$-Level Density: Sketch of proof

Expand Bessel-Kloosterman piece, use GRH to drop non-principal characters, change variables, main term is

$$\frac{b\sqrt{N}}{2\pi m} \int_0^\infty J_{k-1}(x) \hat{\Phi}_n \left( \frac{2 \log(bx\sqrt{N}/4\pi m)}{\log R} \right) \frac{dx}{\log R}$$

with $\Phi_n(x) = \phi(x)^n$.

**Main Idea**

Difficulty in comparison with classical RMT is that instead of having an $n$-dimensional integral of $\phi_1(x_1) \cdots \phi_n(x_n)$ we have a 1-dimensional integral of a new test function. This leads to harder combinatorics but allows us to appeal to the result from ILS.
Results

Theorem (Iyer-Miller-Triantafillou):
The $n$-level densities agree for $\text{supp}(\hat{\phi}) \subset \left( -\frac{1}{n-2}, \frac{1}{n-2} \right)$.

Philosophy:
Number theory harder - adapt tools to get an answer.
Random matrix theory easier - manipulate known answer.

Theorem (ILS)

Let $\Psi$ be an even Schwartz function with $\text{supp}(\hat{\Psi}) \subset (-2, 2)$. Then

$$
\sum_{m \leq N^\epsilon} \frac{1}{m^2} \sum_{(b,N)=1} \frac{R(m^2, b)R(1, b)}{\varphi(b)} \int_0^\infty J_{k-1}(y) \hat{\Psi} \left( \frac{2 \log(by\sqrt{N}/4\pi m)}{\log R} \right) \frac{dy}{\log R}
$$

$$
= -\frac{1}{2} \left[ \int_{-\infty}^\infty \psi(x) \frac{\sin 2\pi x}{2\pi x} \, dx - \frac{1}{2} \psi(0) \right] + O \left( \frac{k \log \log kN}{\log kN} \right),
$$

where $R = k^2 N$, $\varphi$ is Euler's totient function, and $R(n, q)$ is a Ramanujan sum.
Number Theory Side: Iyer-Miller-Triantafillou:
\[ \text{supp}(\tilde{\phi}) \subset \left( -\frac{1}{n-2}, \frac{1}{n-2} \right) \]

Sequence of Lemmas - New Contributions Arise

1. Apply Petersson Formula

2. Restrict Certain Sums

3. Convert Kloosterman Sums to Gauss Sums

4. Remove Non-Principal Characters

5. Convert Sums to Integrals
New Results: Number Theory Side: Iyer-Miller-Triantafillou:

\[ \text{supp}(\hat{\phi}) \subset \left( -\frac{1}{n-2}, \frac{1}{n-2} \right) \]

**Theorem**

*Fix \( n \geq 4 \) and let \( \phi \) be an even Schwartz function with \( \text{supp}(\hat{\phi}) \subset \left( -\frac{1}{n-2}, \frac{1}{n-2} \right) \). Then, the \( n \)th centered moment of the 1-level density for holomorphic cusp forms is*

\[
\begin{align*}
1 & + \frac{(-1)^n}{2} \left( -1 \right)^n (n - 1)!! \left( 2 \int_{-\infty}^{\infty} \hat{\phi}(y)^2 |y| \, dy \right)^{n/2} \\
\pm & \left( -2 \right)^{n-1} \left( \int_{-\infty}^{\infty} \phi(x)^n \frac{\sin 2\pi x}{2\pi x} \, dx - \frac{1}{2} \phi(0)^n \right) \\
\pm & \left( -2 \right)^{n-1} n \left( \int_{-\infty}^{\infty} \hat{\phi}(x_2) \int_{-\infty}^{\infty} \phi^{n-1}(x_1) \frac{\sin(2\pi x_1 (1 + |x_2|))}{2\pi x_1} \, dx_1 \, dx_2 - \frac{1}{2} \phi^n(0) \right).
\end{align*}
\]

Agrees with RMT.
Example: $\text{SO}(\text{even})$

\[
\int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} \hat{\phi}(x_1) \cdots \hat{\phi}(x_n) \det \left( K_1(x_j, x_k) \right)_{1 \leq j, k \leq n} dx_1 \cdots dx_n,
\]

where

\[
K_1(x, y) = \frac{\sin \left( \pi (x - y) \right)}{\pi (x - y)} + \frac{\sin \left( \pi (x + y) \right)}{\pi (x + y)}.
\]

Problem: $n$-dimensional integral - looks very different.
Easier to work with cumulants.

\[
\sum_{n=1}^{\infty} C_n \frac{(it)^n}{n!} = \log \hat{P}(t),
\]

where \( P \) is the probability density function.

\[
\mu'_n = C_n + \sum_{m=1}^{n-1} \binom{n-1}{m-1} C_m \mu'_{n-m},
\]

where \( \mu'_n \) is uncentered moment.
Manipulating determinant expansions leads to analysis of

\[ K(y_1, \ldots, y_n) = \sum_{m=1}^{n} \sum_{\lambda_1 + \ldots + \lambda_m = n, \lambda_j \geq 1} \frac{(-1)^{m+1}}{m} \frac{n!}{\lambda_1! \ldots \lambda_m!} \left( \sum_{\ell=1}^{m} \prod_{\epsilon_j = \pm 1} |\sum_{j=1}^{n} \eta(\ell, j) \epsilon_j y_j| \leq 1 \right), \]

where

\[ \eta(\ell, j) = \begin{cases} +1 & \text{if } j \leq \sum_{k=1}^{\ell} \lambda_k \\ -1 & \text{if } j > \sum_{k=1}^{\ell} \lambda_k. \end{cases} \]
New Result: Iyer-Miller-Triantafillou: Large Support:

$$\text{supp}(\hat{\phi}) \subseteq \left(-\frac{1}{n-2}, \frac{1}{n-2}\right)$$

Hughes-Miller solved for $$\text{supp}(\hat{\phi}) \subseteq \left(-\frac{1}{n-1}, \frac{1}{n-1}\right)$$.

New Complications: If $$\text{supp}(\hat{\phi}) \subseteq \left(-\frac{1}{n-2}, \frac{1}{n-2}\right)$$,

1. $$\eta(\ell, j)\epsilon_j y_j$$ need not have same sign (at most one can differ);

2. more than one term in product can be zero (for fixed $$m, \lambda_j, \epsilon_j$$).

Solution: Double count terms and subtract a correcting term $$\rho_j$$. 
New Result: Iyer-Miller-Triantafillou: Large Support:

\( \text{supp}(\hat{\phi}) \subseteq \left( -\frac{1}{n-2}, \frac{1}{n-2} \right) \)

After Fourier transform identities:

\[
C_{n}^{SO}(\phi) = \frac{(-1)^{n-1}}{2} \left( \int_{-\infty}^{\infty} \phi(x)^{n} \frac{\sin 2\pi x}{2\pi x} dx - \frac{1}{2} \phi(0)^{n} \right) \\
+ \frac{n(-1)^{n}}{2} \left( \int_{-\infty}^{\infty} \hat{\phi}(x_{2}) \int_{-\infty}^{\infty} \phi^{n-1}(x_{1}) \\
\sin(2\pi x_{1}(1 + |x_{2}|)) \frac{dx_{1}dx_{2}}{2\pi x_{1}} - \frac{1}{2} \phi^{n}(0) \right).
\]

Agrees with number theory!
Conclusion and Bibliography
Recap

- Understand compound families in terms of simple ones.

- Choose combinatorics to simplify calculations.

- Extending support often related to deep arithmetic questions.

Moment Formulas for Ensembles of Classical Compact Groups (with Geoffrey Iyer and Nicholas Triantafillou), preprint 2013.
Excised Orthogonal Ensembles
Excised Orthogonal Ensemble: Preliminaries

Characteristic polynomial of $A \in \text{SO}(2N)$ is

$$\Lambda_A(e^{i\theta}, N) := \det(I - Ae^{-i\theta}) = \prod_{k=1}^{N}(1 - e^{i(\theta_k - \theta)})(1 - e^{i(-\theta_k - \theta)}),$$

with $e^{\pm i\theta_1}, \ldots, e^{\pm i\theta_N}$ the eigenvalues of $A$.

Motivated by the arithmetical size constraint on the central values of the $L$-functions, consider Excised Orthogonal Ensemble $T_\chi: A \in \text{SO}(2N)$ with $|\Lambda_A(1, N)| \geq \exp(\chi)$. 
One-Level Densities

One-level density $R_1^{G(N)}$ for a (circular) ensemble $G(N)$:

$$R_1^{G(N)}(\theta) = N \int \ldots \int P(\theta, \theta_2, \ldots, \theta_N) d\theta_2 \ldots d\theta_N,$$

where $P(\theta, \theta_2, \ldots, \theta_N)$ is the joint probability density function of eigenphases.
One-Level Densities

One-level density \( R_1^{G(N)} \) for a (circular) ensemble \( G(N) \):

\[
R_1^{G(N)}(\theta) = N \int \cdots \int P(\theta, \theta_2, \ldots, \theta_N) d\theta_2 \cdots d\theta_N,
\]

where \( P(\theta, \theta_2, \ldots, \theta_N) \) is the joint probability density function of eigenphases. The one-level density excised orthogonal ensemble:

\[
R_1^{T \mathcal{X}}(\theta_1) := C_{\mathcal{X}} \cdot N \int_0^\pi \cdots \int_0^\pi H(\log |\Lambda_A(1, N)| - \mathcal{X}) \times \prod_{j<k} (\cos \theta_j - \cos \theta_k)^2 d\theta_2 \cdots d\theta_N,
\]

with \( H(x) \) the Heaviside function

\[
H(x) = \begin{cases} 
1 & \text{for } x > 0 \\
0 & \text{for } x < 0
\end{cases}
\]

and \( C_{\mathcal{X}} \) is a normalization constant.
One-Level Densities

One-level density $R_{1}^{G(N)}$ for a (circular) ensemble $G(N)$:

$$R_{1}^{G(N)}(\theta) = N \int \ldots \int P(\theta, \theta_2, \ldots, \theta_N) d\theta_2 \ldots d\theta_N,$$

where $P(\theta, \theta_2, \ldots, \theta_N)$ is the joint probability density function of eigenphases. The one-level density excised of the orthogonal ensemble is

$$R_{1}^{T\chi}(\theta_1) = \frac{C_{\chi}}{2\pi i} \int_{c-i\infty}^{c+i\infty} 2^{N r} \frac{\exp(-r\chi)}{r} R_{1}^{J_N}(\theta_1; r - 1/2, -1/2) dr,$$

where $C_{\chi}$ is a normalization constant and

$$R_{1}^{J_N}(\theta_1; r - 1/2, -1/2) = N \int_{0}^{\pi} \ldots \int_{0}^{\pi} \prod_{j=1}^{N} w^{(r-1/2,-1/2)}(\cos \theta_j)$$

$$\times \prod_{j<k}(\cos \theta_j - \cos \theta_k)^2 d\theta_2 \ldots d\theta_N$$

is the one-level density for the Jacobi ensemble $J_N$ with weight function

$$w^{(\alpha,\beta)}(\cos \theta) = (1-\cos \theta)^{\alpha+1/2}(1+\cos \theta)^{\beta+1/2}, \quad \alpha = r - 1/2 \text{ and } \beta = -1/2.$$
With $C_{\chi}$ normalization constant and $P(N, r, \theta)$ defined in terms of Jacobi polynomials,

$$R_{1}^{T_{\chi}}(\theta) = \frac{C_{\chi}}{2\pi i} \int_{c-i\infty}^{c+i\infty} \frac{\exp(-r\chi)}{r} 2^{N^2+2Nr-N} \times$$

$$\times \prod_{j=0}^{N-1} \frac{\Gamma(2+j)\Gamma(1/2+j)\Gamma(r+1/2+j)}{\Gamma(r+N+j)} \times$$

$$\times (1 - \cos \theta)^r \frac{2^{1-r}}{2N+r-1} \frac{\Gamma(N+1)\Gamma(N+r)}{\Gamma(N+r-1/2)\Gamma(N-1/2)} P(N, r, \theta) \, dr.$$

Residue calculus implies $R_{1}^{T_{\chi}}(\theta) = 0$ for $d(\theta, \chi) < 0$ and

$$R_{1}^{T_{\chi}}(\theta) = R_{1}^{SO(2N)}(\theta) + C_{\chi} \sum_{k=0}^{\infty} b_k \exp((k+1/2)\chi) \quad \text{for } d(\theta, \chi) \geq 0,$$

where $d(\theta, \chi) := (2N-1) \log 2 + \log(1 - \cos \theta) - \chi$ and $b_k$ are coefficients arising from the residues. As $\chi \to -\infty$, $\theta$ fixed, $R_{1}^{T_{\chi}}(\theta) \to R_{1}^{SO(2N)}(\theta)$. 
**Figure:** One-level density of excized SO(2N), N = 2 with cut-off $|\Lambda_A(1, N)| \geq 0.1$. The red curve uses our formula. The blue crosses give the empirical one-level density of 200,000 numerically generated matrices.
Theory vs Experiment

Figure: Cumulative probability density of the first eigenvalue from $3 \times 10^6$ numerically generated matrices $A \in SO(2N_{\text{std}})$ with $|\Lambda_A(1, N_{\text{std}})| \geq 2.188 \times \exp(-N_{\text{std}}/2)$ and $N_{\text{std}} = 12$ red dots compared with the first zero of even quadratic twists $L_{E_{11}}(s, \chi_d)$ with prime fundamental discriminants $0 < d \leq 400,000$ blue crosses. The random matrix data is scaled so that the means of the two distributions agree.
Example:
Dirichlet $L$-functions
Dirichlet Characters and $L$-Functions ($m$ prime)

$\left(\mathbb{Z}/m\mathbb{Z}\right)^*$ is cyclic of order $m - 1$ with generator $g$. Let $\zeta_{m-1} = e^{2\pi i/(m-1)}$. The principal character $\chi_0$ is given by

$$\chi_0(k) = \begin{cases} 1 & \text{if } (k, m) = 1 \\ 0 & \text{if } (k, m) > 1. \end{cases}$$

The $m - 2$ primitive characters are determined (by multiplicativity) by action on $g$.

As each $\chi : \left(\mathbb{Z}/m\mathbb{Z}\right)^* \to \mathbb{C}^*$, for each $\chi$ there exists an $l$ such that $\chi(g) = \zeta_{m-1}^l$. Hence for each $l, 1 \leq l \leq m - 2$ we have

$$\chi_l(k) = \begin{cases} \zeta_{m-1}^{la} & k \equiv g^a(m) \\ 0 & (k, m) > 0 \end{cases}$$
Dirichlet Characters and $L$-Functions ($m$ prime)

Let $\chi$ be a primitive character mod $m$. Let

$$c(m, \chi) = \sum_{k=0}^{m-1} \chi(k)e^{2\pi ik/m}.$$  

$c(m, \chi)$ is a Gauss sum of modulus $\sqrt{m}$.

$$L(s, \chi) = \prod_{p} (1 - \chi(p)p^{-s})^{-1}$$

$$\Lambda(s, \chi) = \pi^{-\frac{1}{2}(s+\epsilon)} \Gamma \left( \frac{s + \epsilon}{2} \right) m^{\frac{1}{2}(s+\epsilon)} L(s, \chi),$$

where

$$\epsilon = 0 \text{ if } \chi(-1) = 1 \text{ and } \epsilon = 1 \text{ if } \chi(-1) = -1.$$
Explicit Formula and Expansion

Let $\phi$ be an even Schwartz function with compact support $(-\sigma, \sigma)$, let $\chi$ be a non-trivial primitive Dirichlet character of conductor $m$.

$$
\sum \phi \left( \gamma \frac{\log \left( \frac{m}{\pi} \right)}{2\pi} \right) = \int_{-\infty}^{\infty} \phi(y) \, dy \\
- \sum_p \frac{\log p}{\log (m/\pi)} \hat{\phi} \left( \frac{\log p}{\log (m/\pi)} \right) \left[ \chi(p) + \bar{\chi}(p) \right] p^{-\frac{1}{2}} \\
- \sum_p \frac{\log p}{\log (m/\pi)} \hat{\phi} \left( 2 \frac{\log p}{\log (m/\pi)} \right) \left[ \chi^2(p) + \bar{\chi}^2(p) \right] p^{-1} \\
+ O\left( \frac{1}{\log m} \right).
$$
Explicit Formula and Expansion

\{ \chi_0 \} \cup \{ \chi_l \}_{1 \leq l \leq m-2} \text{ are all the characters mod } m. 
Consider the family of primitive characters mod a prime \( m \) 
\((m - 2 \text{ characters})\):

\[
\int_{-\infty}^{\infty} \phi(y) dy 
- \frac{1}{m-2} \sum_{\chi \neq \chi_0} \left( \sum_{p} \frac{\log p}{\log(m/\pi)} \right) \hat{\phi} \left( \frac{\log p}{\log(m/\pi)} \right) [\chi(p) + \bar{\chi}(p)] p^{-\frac{1}{2}} 
- \frac{1}{m-2} \sum_{\chi \neq \chi_0} \left( \sum_{p} \frac{\log p}{\log(m/\pi)} \right) \hat{\phi} \left( 2 \frac{\log p}{\log(m/\pi)} \right) [\chi^2(p) + \bar{\chi}^2(p)] p^{-1} 
+ O \left( \frac{1}{\log m} \right).
\]

Note can pass Character Sum through Test Function.
Character Sums

\[ \sum_{\chi} \chi(k) = \begin{cases} m - 1 & k \equiv 1(m) \\ 0 & \text{otherwise.} \end{cases} \]

For any prime \( p \neq m \)

\[ \sum_{\chi \neq \chi_0} \chi(p) = \begin{cases} -1 + m - 1 & p \equiv 1(m) \\ -1 & \text{otherwise.} \end{cases} \]

Substitute into

\[ \frac{1}{m-2} \sum_{\chi \neq \chi_0} \sum_p \frac{\log p}{\log(m/\pi)} \hat{\phi} \left( \frac{\log p}{\log(m/\pi)} \right) [\chi(p) + \bar{\chi}(p)] p^{-\frac{1}{2}} \]
First Sum: no contribution if $\sigma < 2$

$$\frac{-2}{m - 2} \sum_{p}^{m^\sigma} \frac{\log p}{\log(m/\pi)} \hat{\phi} \left( \frac{\log p}{\log(m/\pi)} \right) p^{-\frac{1}{2}}$$

$$+ 2 \frac{m - 1}{m - 2} \sum_{p \equiv 1(m)}^{m^\sigma} \frac{\log p}{\log(m/\pi)} \hat{\phi} \left( \frac{\log p}{\log(m/\pi)} \right) p^{-\frac{1}{2}}$$

$$\ll \frac{1}{m} \sum_{p}^{m^\sigma} p^{-\frac{1}{2}} + \sum_{p \equiv 1(m)}^{m^\sigma} p^{-\frac{1}{2}} \ll \frac{1}{m} \sum_{k}^{m^\sigma} k^{-\frac{1}{2}} + \sum_{k \equiv 1(m)}^{m^\sigma} k^{-\frac{1}{2}}$$

$$\ll \frac{1}{m} \sum_{k}^{m^\sigma} k^{-\frac{1}{2}} + \frac{1}{m} \sum_{k}^{m^\sigma} k^{-\frac{1}{2}} \ll \frac{1}{m} m^{\sigma/2}.$$
Second Sum

\[
\frac{1}{m-2} \sum_{\chi \neq \chi_0} \sum_p \frac{\log p}{\log(m/\pi)} \hat{\phi} \left(2 \frac{\log p}{\log(m/\pi)} \right) \frac{\chi^2(p) + \bar{\chi}^2(p)}{p}.
\]

\[
\sum_{\chi \neq \chi_0} [\chi^2(p) + \bar{\chi}^2(p)] = \begin{cases} 
2(m - 2) & p \equiv \pm 1(m) \\
-2 & p \not\equiv \pm 1(m)
\end{cases}
\]
Second Sum

Up to $O\left(\frac{1}{\log m}\right)$ we find that

$$
\ll \frac{1}{m-2} \sum_{p} p^{-1} + \frac{2m-2}{m-2} \sum_{p \equiv \pm 1(m)} p^{-1}
$$

$$
\ll \frac{1}{m-2} \sum_{k} k^{-1} + \sum_{k \equiv 1(m)} k^{-1} + \sum_{k \equiv -1(m)} k^{-1}
$$

$$
\ll \frac{\log(m^{\sigma/2})}{m-2} + \frac{1}{m} \sum_{k} k^{-1} + \frac{1}{m} \sum_{k} k^{-1} + O\left(\frac{1}{m}\right)
$$

$$
\ll \frac{\log m}{m} + \frac{\log m}{m} + \frac{\log m}{m}.
$$
Dirichlet Characters: $m$ Square-free

Fix an $r$ and let $m_1, \ldots, m_r$ be distinct odd primes.

$$m = m_1 m_2 \cdots m_r$$

$$M_1 = (m_1 - 1)(m_2 - 1) \cdots (m_r - 1) = \phi(m)$$

$$M_2 = (m_1 - 2)(m_2 - 2) \cdots (m_r - 2).$$

$M_2$ is the number of primitive characters mod $m$, each of conductor $m$. A general primitive character mod $m$ is given by $\chi(u) = \chi_{l_1}(u)\chi_{l_2}(u) \cdots \chi_{l_r}(u)$. Let $\mathcal{F} = \{\chi : \chi = \chi_{l_1}\chi_{l_2} \cdots \chi_{l_r}\}$.

$$\frac{1}{M_2} \sum_p \frac{\log p}{\log(m/\pi)} \hat{\phi}\left(\frac{\log p}{\log(m/\pi)}\right) p^{-\frac{1}{2}} \sum_{\chi \in \mathcal{F}} [\chi(p) + \bar{\chi}(p)]$$

$$\frac{1}{M_2} \sum_p \frac{\log p}{\log(m/\pi)} \hat{\phi}\left(2\frac{\log p}{\log(m/\pi)}\right) p^{-1} \sum_{\chi \in \mathcal{F}} [\chi^2(p) + \bar{\chi}^2(p)]$$
Dirichlet Characters: $m$ Square-free

\[
\sum_{l_i=1}^{m_i-2} \chi_{l_i}(p) = \begin{cases} 
  m_i - 1 - 1 & p \equiv 1(m_i) \\
  -1 & \text{otherwise.}
\end{cases}
\]

Define

\[
\delta_{m_i}(p, 1) = \begin{cases} 
  1 & p \equiv 1(m_i) \\
  0 & \text{otherwise.}
\end{cases}
\]

Then

\[
\sum_{\chi \in \mathcal{F}} \chi(p) = \sum_{l_1=1}^{m_1-2} \cdots \sum_{l_r=1}^{m_r-2} \chi_{l_1}(p) \cdots \chi_{l_r}(p)
\]

\[
= \prod_{i=1}^{r} \sum_{l_i=1}^{m_i-2} \chi_{l_i}(p) = \prod_{i=1}^{r} \left( -1 + (m_i - 1)\delta_{m_i}(p, 1) \right).
\]
Expansion Preliminaries

$k(s)$ is an s-tuple $(k_1, k_2, \ldots, k_s)$ with $k_1 < k_2 < \cdots < k_s$. This is just a subset of $(1, 2, \ldots, r)$, $2^r$ possible choices for $k(s)$. 

$$\delta_{k(s)}(p, 1) = \prod_{i=1}^{s} \delta_{m_{k_i}}(p, 1).$$

If $s = 0$ we define $\delta_{k(0)}(p, 1) = 1 \forall p$. Then

$$\prod_{i=1}^{r} \left( -1 + (m_i - 1)\delta_{m_i}(p, 1) \right)$$

$$= \sum_{s=0}^{r} \sum_{k(s)} (-1)^{r-s} \delta_{k(s)}(p, 1) \prod_{i=1}^{s} (m_{k_i} - 1).$$
First Sum

\[
\ll \sum_{p} p^{-\frac{1}{2}} \frac{1}{M_2} \left( 1 + \sum_{s=1}^{r} \sum_{k(s)} \delta_k(s)(p, 1) \prod_{i=1}^{s} (m_{k_i} - 1) \right).
\]

As \( m/M_2 \leq 3^r \), \( s = 0 \) sum contributes

\[
S_{1,0} = \frac{1}{M_2} \sum_{p} p^{-\frac{1}{2}} \ll 3^r m_2^{1/2} \sigma^{-1},
\]

hence negligible for \( \sigma < 2 \).
First Sum

\[ \ll \sum_{p} p^{-\frac{1}{2}} \frac{1}{M_2} \left(1 + \sum_{s=1}^{r} \sum_{k(s)} \delta_k(s)(p, 1) \prod_{i=1}^{s} (m_{k_i} - 1)\right). \]

Now we study

\[ S_{1,k(s)} = \frac{1}{M_2} \prod_{i=1}^{s} (m_{k_i} - 1) \sum_{p} p^{-\frac{1}{2}} \delta_k(s)(p, 1) \]

\[ \ll \frac{1}{M_2} \prod_{i=1}^{s} (m_{k_i} - 1) \sum_{n\equiv1(m_{k(s)})} n^{-\frac{1}{2}} \]

\[ \ll \frac{1}{M_2} \prod_{i=1}^{s} (m_{k_i} - 1) \frac{1}{\prod_{i=1}^{s} (m_{k_i})} \sum_{n} n^{-\frac{1}{2}} \ll 3^r m_2^{\frac{1}{2}} \sigma^{-1}. \]
First Sum

There are $2^r$ choices, yielding

$$S_1 \ll 6^r m^{\frac{1}{2} \sigma - 1},$$

which is negligible as $m$ goes to infinity for fixed $r$ if $\sigma < 2$. Cannot let $r$ go to infinity.

If $m$ is the product of the first $r$ primes,

$$\log m = \sum_{k=1}^{r} \log p_k$$

$$= \sum_{p \leq r} \log p \approx r$$

Therefore

$$6^r \approx m^{\log 6} \approx m^{1.79}.$$
Second Sum Expansions and Bounds

\[ \sum_{l_i=1}^{m_i-2} \chi_{l_i}^2(p) = \begin{cases} m_i - 1 - 1 & p \equiv \pm 1(m_i) \\ -1 & \text{otherwise} \end{cases} \]

\[ \sum_{\chi \in \mathcal{F}} \chi^2(p) = \sum_{l_1=1}^{m_1-2} \cdots \sum_{l_r=1}^{m_r-2} \chi_{l_1}^2(p) \cdots \chi_{l_r}^2(p) \]

\[ = \prod_{i=1}^{r} \sum_{l_i=1}^{m_i-2} \chi_{l_i}^2(p) \]

\[ = \prod_{i=1}^{r} \left( -1 + (m_i - 1)\delta_{m_i}(p, 1) + (m_i - 1)\delta_{m_i}(p, -1) \right). \]
Second Sum Expansions and Bounds

Handle similarly as before. Say

\[ p \equiv 1 \mod m_{k_1}, \ldots, m_{k_a} \]
\[ p \equiv -1 \mod m_{k_{a+1}}, \ldots, m_{k_b} \]

How small can \( p \) be?

+1 congruences imply \( p \geq m_{k_1} \cdots m_{k_a} + 1 \).

−1 congruences imply \( p \geq m_{k_{a+1}} \cdots m_{k_b} - 1 \).

Since the product of these two lower bounds is greater than
\[ \prod_{i=1}^{b} (m_{k_i} - 1) \]

at least one must be greater than
\[ \left( \prod_{i=1}^{b} (m_{k_i} - 1) \right)^{\frac{1}{2}}. \]

There are \( 3^r \) pairs, yielding

\[
\text{Second Sum} = \sum_{s=0}^{r} \sum_{k(s)} \sum_{j(s)} S_{2,k(s),j(s)} \ll 9^r m^{-\frac{1}{2}}.
\]
Summary

Agrees with Unitary for $\sigma < 2$ for square-free $m \in [N, 2N]$ from:

**Theorem**

- $m$ square-free odd integer with $r = r(m)$ factors;
- $m = \prod_{i=1}^{r} m_i$;
- $M_2 = \prod_{i=1}^{r} (m_i - 2)$.

Then family $\mathcal{F}_m$ of primitive characters mod $m$ has

$$First \ Sum \ \ll \ \frac{1}{M_2} 2^r m^{\frac{1}{2} \sigma}$$

$$Second \ Sum \ \ll \ \frac{1}{M_2} 3^r m^{\frac{1}{2}}.$$
