Acknowledgements

For many useful discussions:
Sal Baxamusa, Phil Birnbaum, Ray Ciccolella, Steve Johnston, Michelle Manes, Russ Mann.

Dedicated to my great uncle Newt Bromberg:
a lifetime Sox fan who promised me that I would live to see a World Series Championship in Boston.
Goals of the Talk

Derive James’ Pythagorean Won-Loss formula from a reasonable model.

Introduce some of the techniques of modeling.

Discuss the mathematics behind the models and model testing.
Goals of the Talk

Derive James’ Pythagorean Won-Loss formula from a reasonable model.

Introduce some of the techniques of modeling.

Discuss the mathematics behind the models and model testing.

Discuss the 2004 World Champion Boston Red Sox!
Numerical Observation: Pythagorean Won-Loss Formula

Parameters:

- $\text{RS}_{\text{obs}}$: average number of runs scored per game;
- $\text{RA}_{\text{obs}}$: average number of runs allowed per game;
- $\gamma$: some parameter, constant for a sport.

Bill James’ Won-Loss Formula (NUMERICAL Observation):

$$\text{Won} - \text{Loss Percentage} = \frac{\text{RS}_{\text{obs}} \gamma}{\text{RS}_{\text{obs}} \gamma + \text{RA}_{\text{obs}} \gamma}$$

$\gamma$ originally taken as 2, numerical studies show best $\gamma$ is about 1.82.
Applications of the Pythagorean Won-Loss Formula

**Extrapolation:** use half-way through season to predict a team’s performance.

**Evaluation:** see if consistently over-perform or under-perform.

There are other statistics / formulas (example: run-differential per game); advantage is very easy to apply, depends only on two simple numbers for a team.
Probability Review

Probability density:

- $p(x) \geq 0$;
- $\int_{-\infty}^{\infty} p(x) \, dx = 1$;
- $X$ random variable with density $p(x)$: $	ext{Prob} (X \in [a, b]) = \int_{a}^{b} p(x) \, dx$. 
Probability Review

Probability density:

- \( p(x) \geq 0; \)
- \( \int_{-\infty}^{\infty} p(x) \, dx = 1; \)
- \( X \) random variable with density \( p(x) \): \( \text{Prob} (X \in [a, b]) = \int_{a}^{b} p(x) \, dx. \)

Mean (average value) \( \mu = \int_{-\infty}^{\infty} xp(x) \, dx. \)

Variance (how spread out) \( \sigma^2 = \int_{-\infty}^{\infty} (x - \mu)^2 p(x) \, dx. \)
Probability Review

Probability density:

- \( p(x) \geq 0; \)
- \( \int_{-\infty}^{\infty} p(x)\,dx = 1; \)
- \( X \) random variable with density \( p(x) \): \( \text{Prob} (X \in [a, b]) = \int_{a}^{b} p(x)\,dx. \)

Mean (average value) \( \mu = \int_{-\infty}^{\infty} xp(x)\,dx. \)

Variance (how spread out) \( \sigma^2 = \int_{-\infty}^{\infty} (x - \mu)^2 p(x)\,dx. \)

Independence: two random variables are independent if knowledge of one does not give knowledge of the other.
Modeling the Real World

Guidelines for Modeling:

- Model should capture key features of the system;
- Model should be mathematically tractable (solvable).

In general these are conflicting goals. How should we try and model baseball games?
Modeling the Real World

Guidelines for Modeling:

- Model should capture key features of the system;
- Model should be mathematically tractable (solvable).

In general these are conflicting goals. How should we try and model baseball games?

Possible Model:

- Runs Scored and Runs Allowed independent random variables;
- \( f_{RS}(x), g_{RA}(y) \): probability density functions for runs scored (allowed).
- Reduced to calculating

\[
\int_{x} \left[ \int_{y \leq x} f_{RS}(x)g_{RA}(y) \, dy \right] \, dx \quad \text{or} \quad \sum_{i} \left[ \sum_{j < i} f_{RS}(i)g_{RA}(j) \right].
\]
Problems with the Model

Reduced to calculating

\[
\int_x \left[ \int_{y \leq x} f_{RS}(x) g_{RA}(y) \, dy \right] \, dx \quad \text{or} \quad \sum_i \left[ \sum_{j<i} f_{RS}(i) g_{RA}(j) \right].
\]

Problems with the model:

- Can the integral (or sum) be completed in closed form?
- Are the runs scored and allowed independent random variables?
- What are \( f_{RS} \) and \( g_{RA} \)?
Three Parameter Weibull

Weibull distribution:

\[
f(x; \alpha, \beta, \gamma) = \begin{cases} \frac{\gamma}{\alpha} \left( \frac{x-\beta}{\alpha} \right)^{\gamma-1} e^{-\left( \frac{x-\beta}{\alpha} \right)^{\gamma}} & \text{if } x \geq \beta \\ 0 & \text{otherwise.} \end{cases}
\]

- \( \alpha \): scale (variance: meters versus centimeters);
- \( \beta \): origin (mean: translation, zero point);
- \( \gamma \): shape (behavior near \( \beta \) and at infinity).

Various values give different shapes, but can we find \( \alpha, \beta, \gamma \) such that it fits observed data? Is the Weibull theoretically tractable?
Weibull Plots: Parameters \((\alpha, \beta, \gamma)\)

- Red: \((1, 0, 1)\) (exponential)
- Green: \((1, 0, 2)\)
- Cyan: \((1, 2, 2)\)
- Blue: \((1, 2, 4)\)
Weibull Integrations

Let $f(x; \alpha, \beta, \gamma)$ be the probability density of a Weibull($\alpha$, $\beta$, $\gamma$):

$$f(x; \alpha, \beta, \gamma) = \begin{cases} \frac{\gamma}{\alpha} \left( \frac{x-\beta}{\alpha} \right)^{\gamma-1} e^{-((x-\beta)/\alpha)^\gamma} & \text{if } x \geq \beta \\ 0 & \text{otherwise.} \end{cases}$$

For $s \in \mathbb{C}$ with the real part of $s$ greater than 0, recall the $\Gamma$-function:

$$\Gamma(s) = \int_0^\infty e^{-u} u^{s-1} du = \int_0^\infty e^{-u} u^s \frac{du}{u}.$$

$$\Gamma(n) = (n-1)! \quad \text{(i.e., } \Gamma(4) = 3 \cdot 2 \cdot 1 \text{).}$$

Let $\mu_{\alpha, \beta, \gamma}$ denote the mean of $f(x; \alpha, \beta, \gamma)$. 
Weibull Integrations (Continued)

\[ \mu_{\alpha,\beta,\gamma} = \int_{\beta}^{\infty} x \cdot \frac{\gamma}{\alpha} \left( \frac{x - \beta}{\alpha} \right)^{\gamma - 1} e^{-((x-\beta)/\alpha)^\gamma} \, dx \]

\[ = \int_{\beta}^{\infty} \frac{x - \beta}{\alpha} \cdot \frac{\gamma}{\alpha} \left( \frac{x - \beta}{\alpha} \right)^{\gamma - 1} e^{-((x-\beta)/\alpha)^\gamma} \, dx + \beta. \]

Change variables: \( u = (\frac{x-\beta}{\alpha})^{\gamma} \). Then \( du = \frac{\gamma}{\alpha} \left( \frac{x-\beta}{\alpha} \right)^{\gamma - 1} \, dx \) and

\[ \mu_{\alpha,\beta,\gamma} = \int_{0}^{\infty} \alpha u^{\gamma - 1} \cdot e^{-u} \, du + \beta \]

\[ = \alpha \int_{0}^{\infty} e^{-u} u^{1+\gamma^{-1}} \, du + \beta \]

\[ = \alpha \Gamma(1 + \gamma^{-1}) + \beta. \]

A similar calculation determines the variance.
Theorem: Pythagorean Won-Loss Formula: Let the runs scored and allowed per game be two independent random variables drawn from Weibull distributions $(\alpha_{RS}, \beta, \gamma)$ and $(\alpha_{RA}, \beta, \gamma)$; $\alpha_{RS}$ and $\alpha_{RA}$ are chosen so that the means are $RS$ and $RA$. If $\gamma > 0$ then

$$\text{Won-Loss Percentage}(RS, RA, \beta, \gamma) = \frac{(RS - \beta)^\gamma}{(RS - \beta)^\gamma + (RA - \beta)^\gamma}.$$ 

In baseball take $\beta = -.5$ (from runs must be integers).

$RS - \beta$ estimates average runs scored, $RA - \beta$ estimates average runs allowed.
Best Fit Weibulls to Data: Method of Least Squares

Minimized the sum of squares of the error from the runs scored data plus the sum of squares of the error from the runs allowed data.

- Bin\((k)\) is the \(k^{th}\) bin;
- \(RS_{\text{obs}}(k)\) (resp. \(RA_{\text{obs}}(k)\)) the observed number of games with the number of runs scored (allowed) in Bin\((k)\);
- \(A(\alpha, \beta, \gamma, k)\) the area under the Weibull with parameters \((\alpha, \beta, \gamma)\) in Bin\((k)\).

Find the values of \((\alpha_{RS}, \alpha_{RA}, \gamma)\) that minimize

\[
\sum_{k=1}^{\text{#Bins}} (RS_{\text{obs}}(k) - \text{#Games} \cdot A(\alpha_{RS}, -.5, \gamma, k))^2 + \sum_{k=1}^{\text{#Bins}} (RA_{\text{obs}}(k) - \text{#Games} \cdot A(\alpha_{RA}, -.5, \gamma, k))^2.
\]
Best Fit Weibulls to Data (Method of Maximum Likelihood)

Plots of RS (predicted vs observed) and RA (predicted vs observed) for the Boston Red Sox

Using as bins

$$[-0.5, 0.5] \cup [0.5, 1.5] \cup \cdots \cup [7.5, 8.5] \cup [8.5, 9.5] \cup [9.5, 11.5] \cup [11.5, \infty).$$
Plots of RS (predicted vs observed) and RA (predicted vs observed) for the New York Yankees
Plots of RS (predicted vs observed) and RA (predicted vs observed) for the Baltimore Orioles
Plots of RS (predicted vs observed) and RA (predicted vs observed) for the Tampa Bay Devil Rays
Plots of $RS$ (predicted vs observed) and $RA$ (predicted vs observed) for the Toronto Blue Jays
Bonferroni Adjustments

Imagine a fair coin. If flip 1,000,000 times expect 500,000 heads.

Approximately 95% of the time $499,000 \leq \#\text{Heads} \leq 501,000$. 
Bonferroni Adjustments

Imagine a fair coin. If flip 1,000,000 times expect 500,000 heads.

Approximately 95% of the time \(499,000 \leq \text{#Heads} \leq 501,000\).

Consider \(N\) independent experiments of flipping a fair coin 1,000,000 times. What is the probability that at least one of set doesn’t have \(499,000 \leq \text{#Heads} \leq 501,000\)?

γ: mean = 1.74, standard deviation = 0.06, median = 1.76; close to numerically observed value of 1.82.

The mean number of the difference between observed and predicted wins was −0.13 with a standard deviation of 7.11 (and a median of 0.19). If we consider just the absolute value of the difference then we have a mean of 5.77 with a standard deviation of 3.85 (and a median of 6.04).
Conclusions

• Can find parameters such that the Weibulls are good fits to the data;

• The runs scored and allowed per game are statistically independent;

• The Pythagorean Won-Loss Formula is a consequence of our model;

• Method of Least Squares: best value of $\gamma$ of about 1.79;
  Method of Maximum Likelihood: best value of $\gamma$ of about 1.74;
  both are close to the observed best 1.82.
Future Work

- Micro-analysis: runs scored and allowed are not entirely independent (big lead, close game), run production smaller for inter-league games in NL parks, et cetera.

- What about other sports? Does the same model work? How does $\gamma$ depend on the sport?

- Are there other probability distributions that give integrals which can be determined in closed form?

   ◇ A derivation of the Pythagorean Won-Loss Formula in baseball (preprint, 13 pgs).

Appendix: Proof of the Pythagorean Won-Loss Formula

Proof. Let $X$ and $Y$ be independent random variables with Weibull distributions $(\alpha_{RS}, \beta, \gamma)$ and $(\alpha_{RA}, \beta, \gamma)$ respectively.

$$\alpha_{RS} = \frac{RS - \beta}{\Gamma(1 + \gamma^{-1})}, \quad \alpha_{RA} = \frac{RA - \beta}{\Gamma(1 + \gamma^{-1})}.$$ 

We need only calculate the probability that $X$ exceeds $Y$. We use the integral of a probability density is 1.
\[
\text{Prob}(X > Y) = \int_{x=\beta}^{\infty} \int_{y=\beta}^{x} f(x; \alpha_{RS}, \beta, \gamma) f(y; \alpha_{RA}, \beta, \gamma) \, dy \, dx
\]

\[
= \int_{x=\beta}^{\infty} \int_{y=\beta}^{x} \frac{\gamma}{\alpha_{RS}} \left( \frac{x}{\alpha_{RS}} \right)^{\gamma-1} e^{-\left( \frac{x-\beta}{\alpha_{RS}} \right)^{\gamma}} \frac{\gamma}{\alpha_{RA}} \left( \frac{y}{\alpha_{RA}} \right)^{\gamma-1} e^{-\left( \frac{y-\beta}{\alpha_{RA}} \right)^{\gamma}} \, dy \, dx
\]

\[
= \int_{x=0}^{\infty} \frac{\gamma}{\alpha_{RS}} \left( \frac{x}{\alpha_{RS}} \right)^{\gamma-1} e^{-\left( \frac{x}{\alpha_{RS}} \right)^{\gamma}} \left[ \int_{y=0}^{x} \frac{\gamma}{\alpha_{RA}} \left( \frac{y}{\alpha_{RA}} \right)^{\gamma-1} e^{-\left( \frac{y}{\alpha_{RA}} \right)^{\gamma}} \, dy \right] \, dx
\]

\[
= \int_{x=0}^{\infty} \frac{\gamma}{\alpha_{RS}} \left( \frac{x}{\alpha_{RS}} \right)^{\gamma-1} \left[ 1 - e^{-\left( \frac{x}{\alpha_{RA}} \right)^{\gamma}} \right] \, dx, \]

where we have set

\[
\frac{1}{\alpha^{\gamma}} = \frac{1}{\alpha_{RS}^{\gamma}} + \frac{1}{\alpha_{RA}^{\gamma}} = \frac{\alpha_{RS}^{\gamma} + \alpha_{RA}^{\gamma}}{\alpha_{RS}^{\gamma} \alpha_{RA}^{\gamma}}.
\]
\[ \text{Prob}(X > Y) = 1 - \frac{\alpha^\gamma}{\alpha_{RS}^\gamma} \int_0^\infty \frac{\gamma}{\alpha} \left( \frac{x}{\alpha} \right)^{\gamma-1} e^{(x/\alpha)^\gamma} \, dx \]

\[ = 1 - \frac{\alpha^\gamma}{\alpha_{RS}^\gamma} \]

\[ = 1 - \frac{1}{\alpha_{RS}^\gamma} \frac{\alpha_{RS}^\gamma \alpha_{RA}^\gamma}{\alpha_{RS}^\gamma + \alpha_{RA}^\gamma} \]

\[ = \frac{\alpha_{RS}^\gamma}{\alpha_{RS}^\gamma + \alpha_{RA}^\gamma}. \]

We substitute the relations for \( \alpha_{RS} \) and \( \alpha_{RA} \) and find that

\[ \text{Prob}(X > Y) = \frac{(RS - \beta)^\gamma}{(RS - \beta)^\gamma + (RA - \beta)^\gamma}. \]

Note \( RS - \beta \) estimates \( RS_{obs} \), \( RA - \beta \) estimates \( RA_{obs} \).
