Johns Hopkins University, April 4th, 2008
**L-functions**

- Riemann zeta function:

\[
\zeta(s) = \sum_{n=1}^{\infty} \frac{1}{n^s} = \prod_p \left(1 - \frac{1}{p^s}\right)^{-1}.
\]

- Dirichlet $L$-functions:

\[
L(s, \chi_d) = \sum_{n=1}^{\infty} \frac{\chi_d(n)}{n^s} = \prod_p \left(1 - \frac{\chi_d(p)}{p^s}\right)^{-1}.
\]

- Elliptic curve $L$-functions: build up with data related to number of solutions modulo $p$. 
Properties of zeros of \( L \)-functions

- Infinitude of primes, primes in arithmetic progression.

- Chebyshev’s bias: \( \pi_{3,4}(x) \geq \pi_{1,4}(x) \) ‘most’ of the time.

- Birch and Swinnerton-Dyer conjecture.

- Goldfeld, Gross-Zagier: bound for \( h(D) \) from \( L \)-functions with many central point zeros.

- Even better estimates for \( h(D) \) if a positive percentage of zeros of \( \zeta(s) \) are at most \( 1/2 - \epsilon \) of the average spacing to the next zero.
Distribution of zeros

- $\zeta(s) \neq 0$ for $\Re(s) = 1$: $\pi(x)$, $\pi_{a,q}(x)$.
- **GRH**: error terms.
- **GSH**: Chebyshev’s bias.
- **Analytic rank, adjacent spacings**: $h(D)$. 
Measures of Spacings: \( n \)-Level Correlations

\( n \)-level correlation: \( \{\alpha_j\} \) an increasing sequence of numbers, \( B \subset \mathbb{R}^{n-1} \) a compact box:
Measures of Spacings: $n$-Level Density and Families

Let $g_i$ be even Schwartz functions whose Fourier Transform is compactly supported, $L(s, f)$ an $L$-function with zeros $\frac{1}{2} + i\gamma_f$ and conductor $Q_f$:

$$D_{n,f}(g) = \sum_{j_1, \ldots, j_n \atop j_i \neq \pm j_k} g_1 \left( \frac{\gamma_{f,j_1}}{2\pi} \right) \cdots g_n \left( \frac{\gamma_{f,j_n}}{2\pi} \right)$$

- Properties of $n$-level density:
  - Individual zeros contribute in limit
  - Most of contribution is from low zeros
  - Average over similar $L$-functions (family)

- To any geometric family, Katz-Sarnak predict the $n$-level density depends only on a symmetry group (a classical compact group) attached to the family.
$n$-Level Density

$n$-level density: $\mathcal{F} = \bigcup \mathcal{F}_N$ a family of $L$-functions ordered by conductors, $g_k$ an even Schwartz function:

$$D_{n,\mathcal{F}}(g) = \lim_{N \to \infty} \frac{1}{|\mathcal{F}_N|} \sum_{f \in \mathcal{F}_N} \sum_{j_1, \ldots, j_n \neq \pm j_k} g_1 \left( \frac{\log Q_f}{2\pi} \gamma_{j_1; f} \right) \cdots g_n \left( \frac{\log Q_f}{2\pi} \gamma_{j_n; f} \right)$$

As $N \to \infty$, 1-level density converges to

$$\int g(x) W_{1,\mathcal{G}(\mathcal{F})}(x) dx = \int \hat{g}(u) \hat{W}_{1,\mathcal{G}(\mathcal{F})}(u) du.$$

Conjecture (Katz-Sarnak)

(In the limit) Distribution of zeros near central point agrees with distribution of eigenvalues near 1 of a classical compact group.
Let $\mathcal{G}$ be one of the classical compact groups: Unitary, Symplectic, Orthogonal (or $SO($even$)$, $SO($odd$)$). If $\text{supp}(\hat{g}) \subset (-1, 1)$, 1-level density of $\mathcal{G}$ is

$$\hat{g}(0) - c_\mathcal{G} \frac{g(0)}{2},$$

where

$$c_\mathcal{G} = \begin{cases} 
0 & \text{$\mathcal{G}$ is Unitary} \\
1 & \text{$\mathcal{G}$ is Symplectic} \\
-1 & \text{$\mathcal{G}$ is Orthogonal}.
\end{cases}$$
Some Results

- **Orthogonal:**
  - Iwaniec-Luo-Sarnak: 1-level density for $H_k^\pm(N)$, $N$ square-free.
  - Miller, Young: families of elliptic curves.
  - Güloğlu: 1-level for $\{\text{Sym}^r f : f \in H_k(1)\}$, $r$ odd.

- **Symplectic:**
  - Rubinstein: $n$-level densities for $L(s, \chi_d)$.
  - Güloğlu: 1-level for $\{\text{Sym}^r f : f \in H_k(1)\}$, $r$ even.

- **Unitary:**
Identifying the Symmetry Groups

- Often an analysis of the monodromy group in the function field case suggests the answer.
- All simple families studied to date are built from $GL_1$ or $GL_2$ $L$-functions.
- Tools: Explicit Formula, Orthogonality of Characters / Petersson Formula.
- How to identify symmetry group in general? One possibility is by the signs of the functional equation:
- **Folklore Conjecture:** If all signs are even and no corresponding family with odd signs, Symplectic symmetry; otherwise $SO$(even). (False!)
Explicit Formula

- $\pi$: cuspidal automorphic representation on $\text{GL}_n$.
- $Q_\pi > 0$: analytic conductor of $L(s, \pi) = \sum \lambda_\pi(n)/n^s$.
- By GRH the non-trivial zeros are $\frac{1}{2} + i\gamma_{\pi,j}$.
- Satake parameters $\{\alpha_{\pi,i}(p)\}_{i=1}^n$;
  $\lambda_\pi(p^n) = \sum_{i=1}^n \alpha_{\pi,i}(p)^n$.
- $L(s, \pi) = \sum_n \frac{\lambda_\pi(n)}{n^s} = \prod_p \prod_{i=1}^n (1 - \alpha_{\pi,i}(p)p^{-s})^{-1}$.

$$
\sum_j g \left( \gamma_{\pi,j} \frac{\log Q_\pi}{2\pi} \right) = \hat{g}(0) - 2 \sum_{p,\nu} \hat{g} \left( \frac{\nu \log p}{\log Q_\pi} \right) \frac{\lambda_{\pi}(p^{\nu}) \log p}{p^{\nu/2} \log Q_\pi}
$$
Some Results: Rankin-Selberg Convolution of Families

Symmetry constant: \( c_\mathcal{L} = 0 \) (resp, 1 or -1) if family \( \mathcal{L} \) has unitary (resp, symplectic or orthogonal) symmetry.

Rankin-Selberg convolution: Satake parameters for \( \pi_1, p \times \pi_2, p \) are

\[
\{ \alpha_{\pi_1 \times \pi_2}(k) \}_{k=1}^{nm} = \{ \alpha_{\pi_1}(i) \cdot \alpha_{\pi_2}(j) \}_{1 \leq i \leq n}^{1 \leq j \leq m}.
\]

**Theorem (Dueñez-Miller)**

If \( \mathcal{F} \) and \( \mathcal{G} \) are nice families of \( L \)-functions, then

\[
c_{\mathcal{F} \times \mathcal{G}} = c_{\mathcal{F}} \cdot c_{\mathcal{G}}.
\]
Ratios Conjecture
Farmer (1993): Considered

\[
\int_0^T \frac{\zeta(s + \alpha)\zeta(1 - s + \beta)}{\zeta(s + \gamma)\zeta(1 - s + \delta)} \, dt,
\]

conjectured (for appropriate values)

\[
T \frac{(\alpha + \delta)(\beta + \gamma)}{\alpha + \beta)(\gamma + \delta)} - T^{1-\alpha-\beta} \frac{(\delta - \beta)(\gamma - \alpha)}{(\alpha + \beta)(\gamma + \delta)}.
\]

Conrey-Farmer-Zirnbauer (2007): conjecture formulas for averages of products of \(L\)-functions over families:

\[
R_F = \sum_{f \in F} \omega_f \frac{L \left( \frac{1}{2} + \alpha, f \right)}{L \left( \frac{1}{2} + \gamma, f \right)}.
\]
Uses of the Ratios Conjecture

- **Applications:**
  - $n$-level correlations and densities;
  - mollifiers;
  - moments;
  - vanishing at the central point;

- **Advantages:**
  - RMT models often add arithmetic ad hoc;
  - predicts lower order terms, often to square-root level.
Inputs for 1-level density

Approximate Functional Equation:

\[ L(s, f) = \sum_{m \leq x} \frac{a_m}{m^s} + \epsilon X_L(s) \sum_{n \leq y} \frac{a_n}{n^{1-s}}; \]

- \( \epsilon \) sign of the functional equation,
- \( X_L(s) \) ratio of \( \Gamma \)-factors from functional equation.

Explicit Formula: \( g \) Schwartz test function,

\[ \sum_{f \in \mathcal{F}} \sum_{\gamma} \omega_f g \left( \gamma \frac{\log N_f}{2\pi} \right) = \frac{1}{2\pi i} \int_{(c)} - \int_{(1-c)} R'_{\mathcal{F}}(\cdots)g(\cdots) \]

- \( R'_{\mathcal{F}}(r) = \frac{\partial}{\partial \alpha} R_{\mathcal{F}}(\alpha, \gamma) \bigg|_{\alpha=\gamma=r}. \)
Procedure

- Use approximate functional equation to expand numerator.
- Expand denominator by generalized Mobius function: cusp form

\[
\frac{1}{L(s, f)} = \sum_h \frac{\mu_f(h)}{h^s},
\]

where \(\mu_f(h)\) is the multiplicative function equaling 1 for \(h = 1\), \(-\lambda_f(p)\) if \(n = p\), \(\chi_0(p)\) if \(h = p^2\) and 0 otherwise.
- Execute the sum over \(\mathcal{F}\), keeping only main (diagonal) terms.
- Extend the \(m\) and \(n\) sums to infinity (complete the products).
- Differentiate with respect to the parameters.
Main Results
Symplectic Families

- Fundamental discriminants: $d$ square-free and 1 modulo 4, or $d/4$ square-free and 2 or 3 modulo 4.
- Associated character $\chi_d$:
  - $\chi_d(-1) = 1$ say $d$ even;
  - $\chi_d(-1) = -1$ say $d$ odd.
  - even (resp., odd) if $d > 0$ (resp., $d < 0$).

Will study following families:

- even fundamental discriminants at most $X$;
- $\{8d : 0 < d \leq X, \ d \text{ an odd, positive square-free fundamental discriminant}\}$. 
Prediction from Ratios Conjecture

\[
\frac{1}{X^*} \sum_{d \leq X} \sum_{\gamma_d} g\left(\gamma_d \frac{\log X}{2\pi}\right) = \frac{1}{X^* \log X} \int_{-\infty}^{\infty} g(\tau) \sum_{d \leq X} \left[ \log \frac{d}{\pi} + \frac{1}{2} \frac{\Gamma'}{\Gamma} \left( \frac{1}{4} \pm \frac{i\pi \tau}{\log X} \right) \right] d\tau \\
+ \frac{2}{X^* \log X} \sum_{d \leq X} \int_{-\infty}^{\infty} g(\tau) \left[ \frac{\zeta'}{\zeta} \left( 1 + \frac{4\pi i\tau}{\log X} \right) + A_D' \left( \frac{2\pi i\tau}{\log X} ; \frac{2\pi i\tau}{\log X} \right) \right] d\tau \\
- e^{-2\pi i\tau \log(d/\pi)/\log X} \sum_{\gamma_d} \frac{\Gamma\left(\frac{1}{4} - \frac{\pi i\tau}{\log X}\right)}{\Gamma\left(\frac{1}{4} + \frac{\pi i\tau}{\log X}\right)} \zeta\left(1 - \frac{4\pi i\tau}{\log X}\right) A_D \left( \frac{2\pi i\tau}{\log X} ; \frac{2\pi i\tau}{\log X} \right) \right) d\tau + O(X^{-\frac{1}{2} + \epsilon}),
\]

with

\[
A_D(-r, r) = \prod_p \left(1 - \frac{1}{(p + 1)p^{1-2r}} - \frac{1}{p + 1}\right) \cdot \left(1 - \frac{1}{p}\right)^{-1}
\]

\[
A_D'(r; r) = \sum_p \frac{\log p}{(p + 1)(p^{1+2r} - 1)}.
\]
Prediction from Ratios Conjecture

Main term is

$$\frac{1}{X^*} \sum_{d \leq X} \sum_{\gamma_d} g \left( \gamma_d \frac{\log X}{2\pi} \right) = \int_{-\infty}^{\infty} g(x) \left( 1 - \frac{\sin(2\pi x)}{2\pi x} \right) \, dx$$

$$+ \, O \left( \frac{1}{\log X} \right),$$

which is the 1-level density for the scaling limit of USp(2N). If \( \text{supp}(\hat{g}) \subset (-1, 1) \), then the integral of \( g(x) \) against \( -\sin(2\pi x)/2\pi x \) is \( -g(0)/2 \).
Prediction from Ratios Conjecture

Assuming RH for $\zeta(s)$, for $\text{supp}(\hat{g}) \subset (-\sigma, \sigma) \subset (-1, 1)$:

$$\frac{-2}{X \log X} \sum_{d \leq X} \int_{-\infty}^{\infty} g(\tau) \ e^{-2\pi i \tau \frac{\log(d/\pi)}{\log X}} \frac{\Gamma \left( \frac{1}{4} - \frac{\pi i \tau}{\log X} \right)}{\Gamma \left( \frac{1}{4} + \frac{\pi i \tau}{\log X} \right)} \zeta \left( 1 - \frac{4\pi i \tau}{\log X} \right) A_D \left( -\frac{2\pi i \tau}{\log X}; \frac{2\pi i \tau}{\log X} \right) d\tau$$

$$= -\frac{g(0)}{2} + O(X^{-\frac{3}{4}(1-\sigma)+\epsilon});$$

the error term may be absorbed into the $O(X^{-1/2+\epsilon})$ error if $\sigma < 1/3$. 
Theorem (M– ’07)

Let $\text{supp}(\hat{g}) \subset (-\sigma, \sigma)$, assume RH for $\zeta(s)$. 1-Level Density agrees with prediction from Ratios Conjecture

- up to $O(X^{-(1-\sigma)/2+\epsilon})$ for the family of quadratic Dirichlet characters with even fundamental discriminants at most $X$;
- up to $O(X^{-1/2} + X^{-(1-3/2\sigma)+\epsilon} + X^{-3/4(1-\sigma)+\epsilon})$ for our sub-family. If $\sigma < 1/3$ then agrees up to $O(X^{-1/2+\epsilon})$. 
Numerics (J. Stopple): 1,003,083 negative fundamental discriminants \(-d \in [10^{12}, 10^{12} + 3.3 \cdot 10^6]\)

Histogram of normalized zeros (\(\gamma \leq 1\), about 4 million).

- Red: main term.
- Blue: includes \(O(1/\log X)\) terms.
- Green: all lower order terms.
Sketch of Proofs
Ratios Calculation

Hardest piece to analyze is

\[
R(g; X) = -\frac{2}{X^* \log X} \sum_{d \leq X} \int_{-\infty}^{\infty} g(\tau) e^{-2\pi i \tau \log(d/X)} \frac{\Gamma \left( \frac{1}{4} - \frac{\pi i \tau}{\log X} \right)}{\Gamma \left( \frac{1}{4} + \frac{\pi i \tau}{\log X} \right)} \\
\cdot \zeta \left( 1 - \frac{4\pi i \tau}{\log X} \right) A_D \left( -\frac{2\pi i \tau}{\log X}; \frac{2\pi i \tau}{\log X} \right) d\tau,
\]

\[
A_D(-r, r) = \prod_p \left( 1 - \frac{1}{(p+1)p^{1-2r}} - \frac{1}{p+1} \right) \cdot \left( 1 - \frac{1}{p} \right)^{-1}.
\]

Proof: shift contours, keep track of poles of ratios of \( \Gamma \) and zeta functions.
Ratios Calculation: Weaker result for $\text{supp}(\hat{g}) \subset (-1, 1)$.

- $d$-sum is $X^* e^{-2\pi i (1 - \frac{\log \pi}{\log X})} \left( 1 - \frac{2\pi i \tau}{\log X} \right)^{-1} + O(X^{1/2})$;

- decay of $g$ restricts $\tau$-sum to $|\tau| \leq \log X$, Taylor expand everything but $g$: small error term and

\[
\int_{|\tau| \leq \log X} g(\tau) \sum_{n=-1}^{N} \frac{a_n}{\log^n X} (2\pi i \tau)^n e^{-2\pi i (1 - \frac{\log \pi}{\log X}) \tau} \, d\tau
\]

\[
= \sum_{n=-1}^{N} \frac{a_n}{\log^n X} \int_{|\tau| \leq \log X} (2\pi i \tau)^n g(\tau) e^{-2\pi i (1 - \frac{\log \pi}{\log X}) \tau} \, d\tau;
\]

- from decay of $g$ can extend the $\tau$-integral to $\mathbb{R}$ (essential that $N$ is fixed and finite!), for $n \geq 0$ get the Fourier transform of $g^{(n)}$ (the $n^{\text{th}}$ derivative of $g$) at $1 - \frac{\pi}{\log X}$, vanishes if $\text{supp}(\hat{g}) \subset (-1, 1)$.
Number Theory Sums

\[ S_{\text{even}} = - \frac{2}{X^*} \sum_{d \leq X} \sum_{\ell=1}^{\infty} \sum_{p} \frac{\chi_d(p)^2 \log p}{p^\ell \log X} \hat{g} \left( \frac{2 \log p^\ell}{\log X} \right) \]

\[ S_{\text{odd}} = - \frac{2}{X^*} \sum_{d \leq X} \sum_{\ell=0}^{\infty} \sum_{p} \frac{\chi_d(p) \log p}{p^{(2\ell+1)/2} \log X} \hat{g} \left( \frac{\log p^{2\ell+1}}{\log X} \right) . \]
Lemma

Let $\text{supp}(\hat{g}) \subset (-\sigma, \sigma) \subset (-1, 1)$. Then

\[ S_{\text{even}} = -\frac{g(0)}{2} + \frac{2}{\log X} \int_{-\infty}^{\infty} g(\tau) \frac{\zeta'}{\zeta} \left(1 + \frac{4\pi i \tau}{\log X}\right) d\tau \]

\[ + \frac{2}{\log X} \int_{-\infty}^{\infty} g(\tau) A_D' \left(\frac{2\pi i \tau}{\log X}; \frac{2\pi i \tau}{\log X}\right) + O(X^{-\frac{1}{2}+\epsilon}) \]

\[ S_{\text{odd}} = O(X^{\frac{1-\sigma}{2}} \log^6 X). \]

If instead we consider the family of characters $\chi_{8d}$ for odd, positive square-free $d \in (0, X)$ (d a fundamental discriminant), then

\[ S_{\text{odd}} = O(X^{-1/2+\epsilon} + X^{-(1-\frac{3}{2}\sigma)+\epsilon}). \]
Analysis of $S_{\text{even}}$

\[ \chi_d(p)^2 = 1 \] except when $p|d$. Replace $\chi_d(p)^2$ with 1, and subtract off the contribution from when $p|d$:

\[
S_{\text{even}} = -2 \sum_{\ell=1}^{\infty} \sum_p \frac{\log p}{p^\ell \log X} \hat{g} \left( 2 \frac{\log p^\ell}{\log X} \right) \\
+ \frac{2}{X^*} \sum_{d \leq X} \sum_{\ell=1}^{\infty} \sum_p \frac{\log p}{p^\ell \log X} \hat{g} \left( 2 \frac{\log p^\ell}{\log X} \right) \\
= S_{\text{even};1} + S_{\text{even};2}.
\]

Lemma (Perron’s Formula)

\[
S_{\text{even};1} = -\frac{g(0)}{2} + \frac{2}{\log X} \int_{-\infty}^{\infty} g(\tau) \frac{\zeta'}{\zeta} \left( 1 + \frac{4\pi i \tau}{\log X} \right) d\tau.
\]
Analysis of $S_{\text{even}}: S_{\text{even};2}$

This piece gives us $\int g(\tau)A'_D(\cdot \cdot \cdot , \cdot \cdot \cdot )$.

- **Main ideas:**
  - Restrict to $p \leq X^{1/2}$.
  - For $p < X^{1/2}$: $\sum_{d \leq X, p|d} 1 = \frac{X^*}{p+1} + O(X^{1/2})$.
  - Use Fourier Transform to expand $\hat{g}$. 

Analysis of $S_{\text{odd}}$

\[ S_{\text{odd}} = -\frac{2}{X^*} \sum_{\ell=0}^{\infty} \sum_{p} \frac{\log p}{p^{(2\ell+1)}/2 \log X} \hat{g} \left( \frac{\log p^{2\ell+1}}{\log X} \right) \sum_{d \leq X} \chi_d(p). \]

**Jutila’s bound**

\[
\left| \sum_{1 < n \leq N} \chi_d(n) \right|^2 \ll NX \log^{10} N.
\]

Proof: Cauchy-Schwarz and Jutila: $p^{2\ell+1}$ non-square:

\[
\left( \sum_{\ell=0}^{\infty} \sum_{p^{(2\ell+1)}/2 \leq X^{\sigma}} \left| \sum_{d \leq X} \chi_d(p) \right|^2 \right)^{1/2} \ll X^{1+\sigma/2} \log^5 X.
\]
Analysis of $S_{\text{odd}}$: Extending Support

More technical, replace Jutila’s bound by applying Poisson Summation to character sums.

**Lemma**

Let $\text{supp}(\hat{g}) \subset (-\sigma, \sigma) \subset (-1, 1)$. For family $\{8d : 0 < d \leq X, \ d \text{ an odd, positive square-free fundamental discriminant}\}$, $S_{\text{odd}} = O(X^{-\frac{1}{2}+\epsilon} + X^{-\left(1-\frac{3}{2}\sigma\right)+\epsilon})$.

In particular, if $\sigma < 1/3$ then $S_{\text{odd}} = O(X^{-1/2+\epsilon})$. 
Conclusions
Conclusions

- Ratios Conjecture gives detailed predictions (up to $X^{1/2+\epsilon}$).

- Number Theory agrees with predictions for suitably restricted test functions.

- Numerics quite good.
Appendix
RH and the Prime Number Theorem

From \( \zeta(s) = \sum n^{-s} = \prod_p (1 - p^{-s})^{-1} \), logarithmic derivative is

\[
-\frac{\zeta'(s)}{\zeta(s)} = \sum \frac{\Lambda(n)}{n^s},
\]

where \( \Lambda(n) = \log p \) if \( n = p^k \) and is 0 otherwise.

Take Mellin transform, integrate and shift contour. Find

\[
\sum_{n \leq x} \Lambda(n) = x - \sum \frac{x^\rho}{\rho},
\]

where \( \rho = 1/2 + i\gamma \) runs over non-trivial zeros of \( \zeta(s) \).

Partial summation gives Prime Number Theorem (to first order, there are \( x / \log x \) primes at most \( x \)) if \( \Re \rho < 1 \).

The smaller max \( \Re(\rho) \) is, the better the error term in the Prime Number Theorem. The Riemann Hypothesis (RH) says \( \Re(\rho) = 1/2 \).
Primes in Arithmetic Progression

To study number primes $p \equiv a \mod q$, use

$$L(s, \chi) = \sum \frac{\chi(n)}{n^s} = \prod_p \left(1 - \frac{\chi(p)}{p^s}\right)^{-1}.$$ 

Key sum: $\frac{1}{\phi(q)} \sum_{\chi \mod q} \chi(n)$ is 1 if $n \equiv 1 \mod q$ and 0 otherwise.

Similar arguments give

$$\sum_{p \equiv a \mod q} \frac{\log p}{p^s} = -\frac{1}{\phi(q)} \sum_{\chi \mod q} \frac{L'(s, \chi)}{L(s, \chi)} \chi(\overline{a}) + \text{Good}(s).$$

Note: To understand $\{p \equiv a \mod q\}$ need to understand all $L(s, \chi)$; see benefit of studying a family.
GSH and Chebyshev’s Bias

\[ \pi_{3,4}(x) \geq \pi_{1,4}(x) \] and \[ \pi_{2,3}(x) \geq \pi_{1,3}(x) \] ‘most’ of the time. Use analytic density:

\[ \text{Den}_{\text{an}}(S) = \limsup \frac{1}{\log T} \int_{S \cap [2,T]} \frac{dt}{t}. \]

Have \[ \pi_{3,4}(x) \geq \pi_{1,4}(x) \] with analytic density .9959 (first flip at 26861); \[ \pi_{2,3}(x) \geq \pi_{1,3}(x) \] with analytic density .9990 (first flip \( \approx 6 \cdot 10^{11} \)).

Non-residues beat residues. Key ingredient Generalized Simplicity Hypothesis (GSH): the zeros of \( L(s, \chi) \) are linearly independent over \( \mathbb{Q} \).

Structure of zeros important: GSH used to show a flow on a torus is full (becomes equidistributed).
Class Number

Class number: measures failure of unique factorization (order of ideal class group).

Imaginary quadratic field $\mathbb{Q}(\sqrt{D})$, fundamental discriminant $D < 0$, $I$ group of non-zero fractional ideals, $P$ subgroup of principal ideals, $\mathcal{H} = I/P$ class group, $h(D) = \#\mathcal{H}$ the class number. Dirichlet proved

$$L(1, \chi_D) = \frac{2\pi h(D)}{w_D \sqrt{D}},$$

where $\chi_D$ the quadratic character and $w_D = 2$ if $D < -4$, $4$ if $D = -4$ and $6$ if $D = -3$.

Theorem: $h(D) = 1 \iff -D \in \{3, 4, 7, 8, 11, 19, 43, 67, 163\}$. 
Expect \( \frac{\sqrt{|D|}}{\log \log |D|} \ll h(D) \ll \sqrt{|D|} \log \log |D| \). Siegel proved \( h(D) > c(\epsilon)|D|^{1/2-\epsilon} \) (but ineffective).

Goldfeld, Gross-Zagier: \( f \) primitive cusp form of weight \( k \), level \( N \), trivial central character, suppose \( m = \text{ord}_{s=1/2} L(s, f)L(s, \chi_D) \geq 3 \), \( g = m - 1 \) or \( m - 2 \) so that \( (-1)^g = \omega(f)\omega(f_{\chi_D}) \) (signs of final eqs). Then have effective bound

\[
h(D) \gg (\log |D|)^{g-1} \prod_{p|D} \left(1 + \frac{1}{p}\right)^{-3} \left(1 + \frac{\lambda(p) \sqrt{p}}{p+1}\right)^{-1}.
\]

Good result from using an elliptic curve that vanishes to order 3 at \( s = 1/2 \), application of many zeros at central point.
Assume a positive percent of zeros (or \( c T \log T / (\log |D|)^A \)) of zeros with \( \gamma \leq T \) of \( \zeta(s) \) are at most \( 1/2 - \epsilon \) of the average spacing from the next zero \( \zeta(s) \). Then \( h(D) \gg \sqrt{|D|} / (\log |D|)^B \), all constants computable.

See actual spacings between zeros are tied to number theory (have positive percent are less than half the average spacing if GUE Conjecture holds for adjacent spacings).

Instead of \( 1/2 - \epsilon \), under RH have: .68 (Montgomery), .5179 (Montgomery-Odlyzko), .5171 (Conrey-Ghosh-Gonek), .5169 (Conrey-Iwaniec) (Montgomery says led to pair correlation conjecture by looking at gaps between zeros of \( \zeta(s) \) and \( h(D) \)).
